

NOT GETTING LOST IN TRANSLATION

Outline

- The beginnings
- Let's talk
- A new library
- A new world
- What now
- An experiment
- Move on

ABOUT ME

- Electrical engineer
- Build computers and create software for more than 40 years
- Develop hardware and software in the field of applied digital signal processing for 30 years
- Member of the C++ committee (learning novice) for 4 years (EWG, SG15)

- employed by

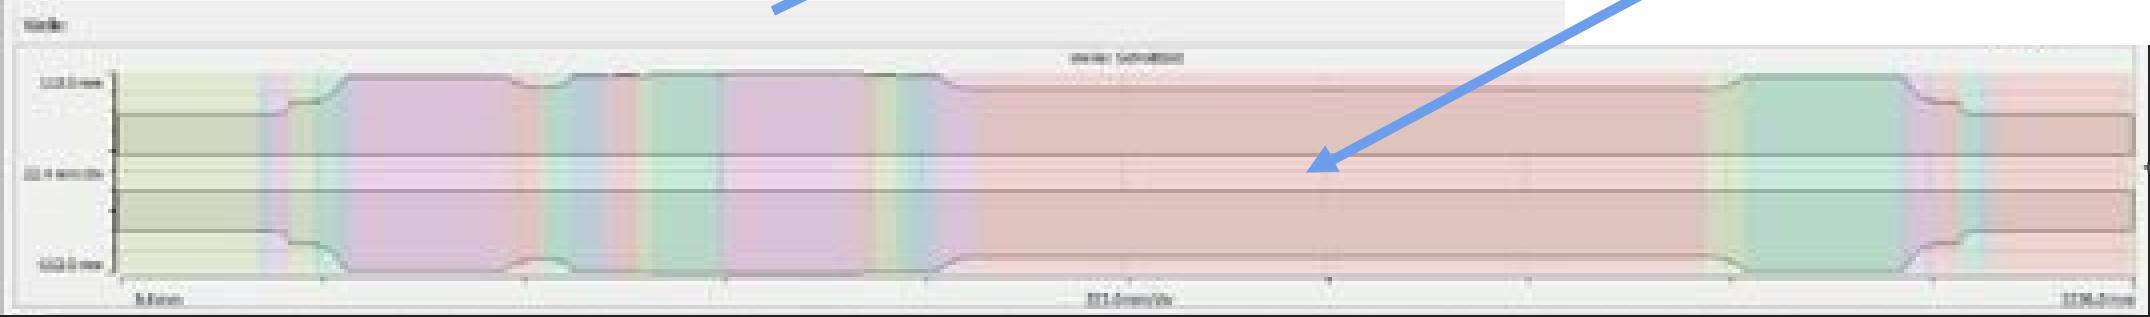

TIMELINE

2009

Boost::format
German only

STARTUP CULTURE

Features! More features!

Get a name!

Get the architecture right!

BOOST::FORMAT

Why?

- it's compatible to C's printf() family
- it's different from C's printf() family
- it supports **advanced** formatting specifiers
- it "creatively" uses operators to **separate** the formatting specification from the arguments
- it supports formatting of **user-defined types**
- it supports stream manipulators

Example:

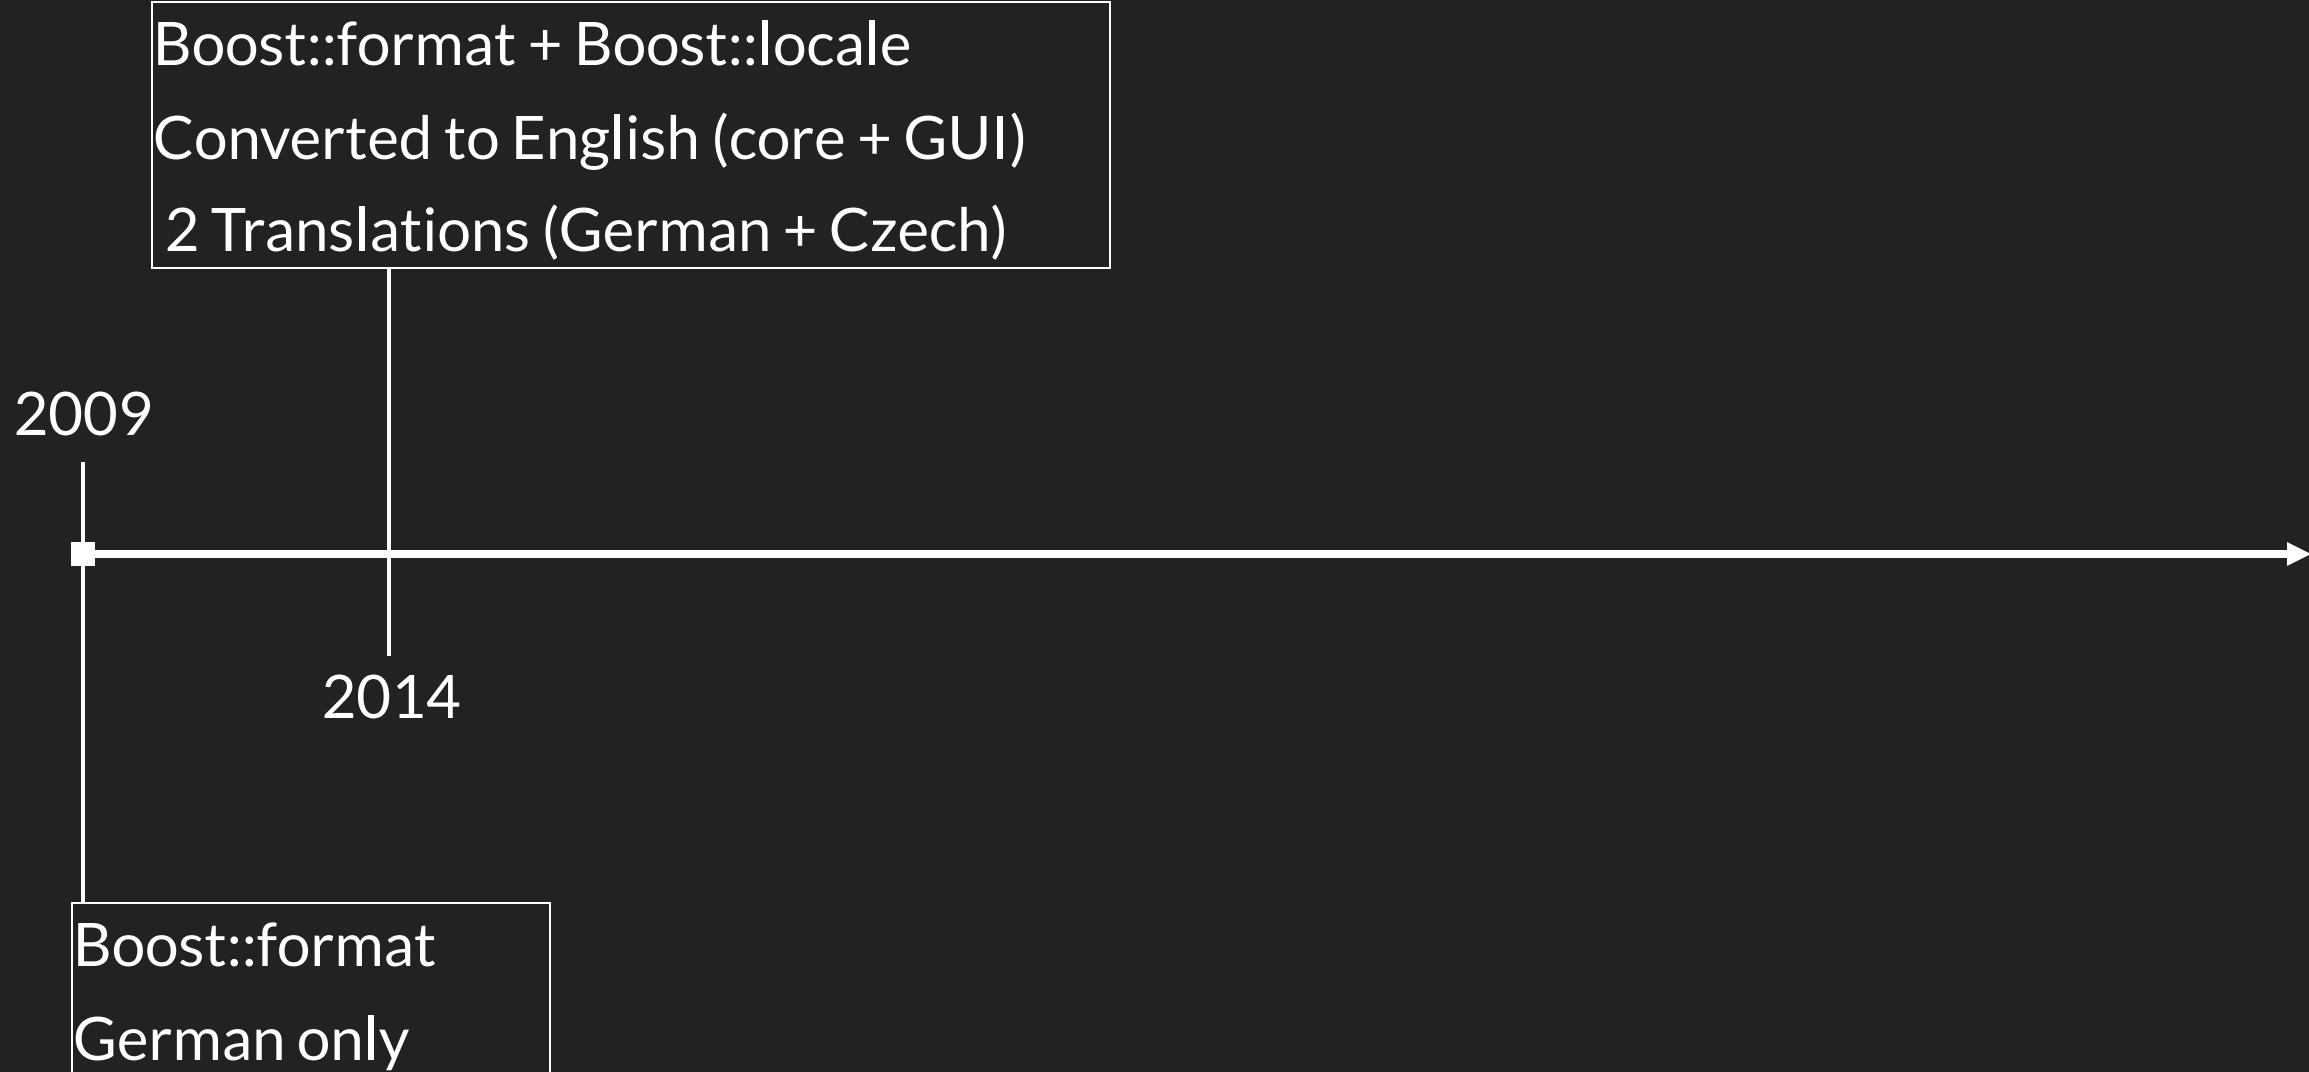

```
#include <boost/format.hpp>

std::cout << boost::format("formatting specifier") % argument1 % argument2;
```

let's talk

TIMELINE

STRING TRANSLATION

Questions

- which translation system?
- is it **mature**?
- does it have an ecosystem?
 - **editors**
 - tools
 - build system
- does it **fit**? Does it feel "natural"?
- can it be used by **end users**?
 - domain experts
 - not even remotely firm in IT

TRANSLATION FORMAT

Binary

XML

JSON

Text

GETTEXT

pretty standard, available on all major platforms

two major implementations

- GNU gettext
- Boost::locale

both rely on C locales (or their C++ equivalents) and message catalogs

P2918 brings GNU gettext as a striking example to support runtime format strings!

TOOLS

step 1: mark translatable text

```
#include <boost/format.hpp>

std::cout << boost::format("formatting specifier") % argument1 % argument2;
```

```
#include <boost/format.hpp>
#include <boost/locale/message.hpp>
using boost::message::translate

std::cout << boost::format(translate("formatting specifier")) % argument1 % argument2;
```

step 2: scan source files with 'xgettext' for marked text

```
$(Keyword) is e.g. "translate"
```

```
xgettext --keyword --keyword=$(Keyword):1,1t --keyword=$(Keyword):1c,2,2t --keyword=$(Keyword):1,2,3t
--keyword=$(Keyword):1c,2,3,4t a.cpp b.cpp c.hpp ...
```

TOOLS

Result: a so-called PO **template** file

- language **agnostic**
- transient

```
# SOME DESCRIPTIVE TITLE.
# Copyright (C) YEAR THE PACKAGE'S COPYRIGHT HOLDER
# This file is distributed under the same license as the PACKAGE package.
# FIRST AUTHOR <EMAIL@ADDRESS>, YEAR.
#
#, fuzzy
msgid ""
msgstr ""
"MIME-Version: 1.0\n"
"Content-Type: text/plain; charset=CHARSET\n"
"Content-Transfer-Encoding: 8bit\n"
"Plural-Forms: nplurals=INTEGER; plural=EXPRESSION;\n"
#: main.cpp
msgctxt "(optional context)"
msgid "singular"
msgid_plural "(optional plural)"
msgstr[0] ""
msgstr[1] ""
```

MO' TOOLS

step 3: each template is then processed into individual translation files,
one for each **country, region, specialties**

- msguniq
- msgmerge
- msgattrib

The result is a collection of **PO (portable object) files**

- specific to language, country, region, company
- **stable**
- checked into repositories

you can have **multiple** of them, e.g. one for each subsystem

PO FILE CONTENT

```
1 #
2 msgid ""
3 msgstr ""
4 "Project-Id-Version: Example 1.0\n"
5 "Report-Msgid-Bugs-To: somebody@example.com\n"
6 "POT-Creation-Date: \n"
7 "PO-Revision-Date: 2024-04-30 11:38+0200\n"
8 "Last-Translator: EMAIL@ADDRESS\n"
9 "Language-Team: Czech\n"
10 "Language: cs\n"
11 "MIME-Version: 1.0\n"
12 "Content-Type: text/plain; charset=UTF-8\n"
13 "Content-Transfer-Encoding: 8bit\n"
14 "Plural-Forms: nplurals=3; plural=(n==1 ? 0 : n>=2 && n<=4 ? 1 : 2);\n"
15 "X-Generator: Poedit 3.4.2\n"
16
17 # This is only a example
18 #: main.cpp
19 msgctxt "Disambiguation"
20 msgid "Singular"
21 msgid_plural "Plural"
22 msgstr[0] "Singulární"
23 msgstr[1] "Duální"
24 msgstr[2] "Plurál"
```

EVEN MORE TOOLS

step 4: (possibly) combine multiple PO files and compile them to the target directory, in the target format

- msgmerge
- msgfmt

This checks the **validity** of format specifiers and placeholders!

The result is a collection of **MO (machine object) files**

- specific to language, country, region, company
- binary
- optimized for consumption
- distributed to the customer's machine

The format is described in the manual:

<https://www.gnu.org/software/gettext/manual/gettext.html#MO-Files>

```

1      byte 0 | magic number = 0x950412de
2      4 | file format revision = 0
3
4      8 | number of strings           == N
5
6      12 | offset of table with original strings == O
7
8      16 | offset of table with translation strings == T
9
10     20 | size of hashing table       == S
11
12     24 | offset of hashing table     == H
13
14
15
16     .
17     .   (possibly more entries later)
18     .
19
20     0 | length & offset 0th string  -----
21     0 + 8 | length & offset 1st string  -----
22     ...
23 0 + ((N-1)*8) | length & offset (N-1)th string  ...
24
25     T | length & offset 0th translation  -----
26     T + 8 | length & offset 1st translation  -----
27     ...
28 T + ((N-1)*8) | length & offset (N-1)th translation  ...
29
30     H | start hash table
31     ...
32  H + S * 4 | end hash table
33
34     NUL terminated 0th string <-----
35
36     NUL terminated 1st string <-----
37
38     ...
39
40     NUL terminated 0th translation <-----
41
42     NUL terminated 1st translation <-----
43
44     ...
45
46

```

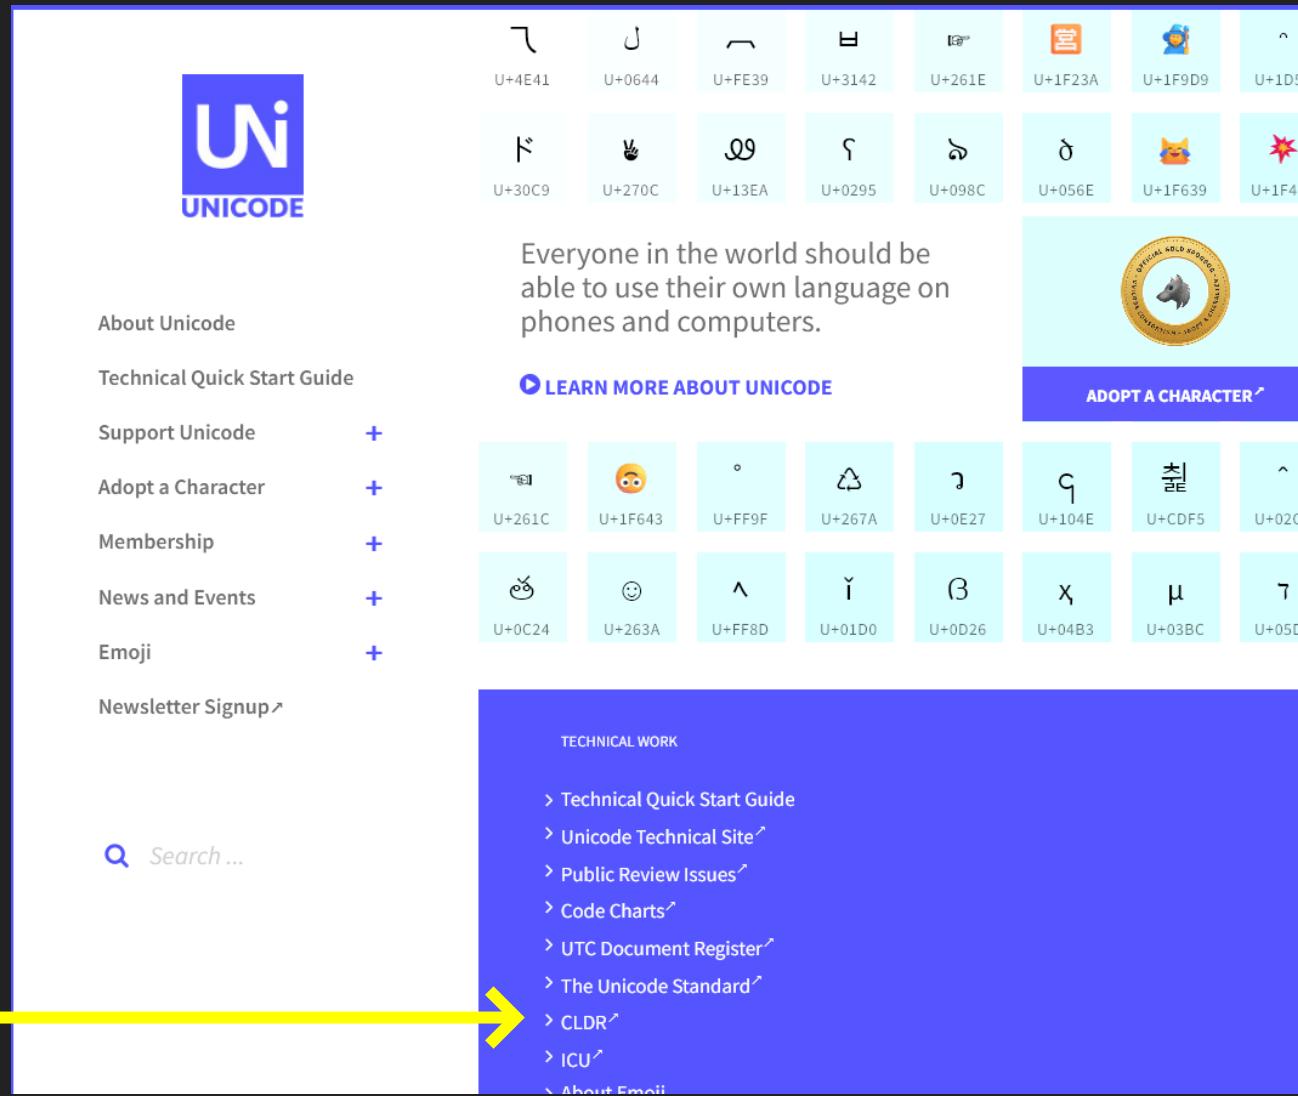

MO FILE CONTENT

- Header
- two string offset tables
 - original (contains context)
 - translated
- optional, unspecified hashing table
- all language forms (i.e. plurals) are NUL separated!

Every entry (besides strings) is a **4-byte unsigned integer**

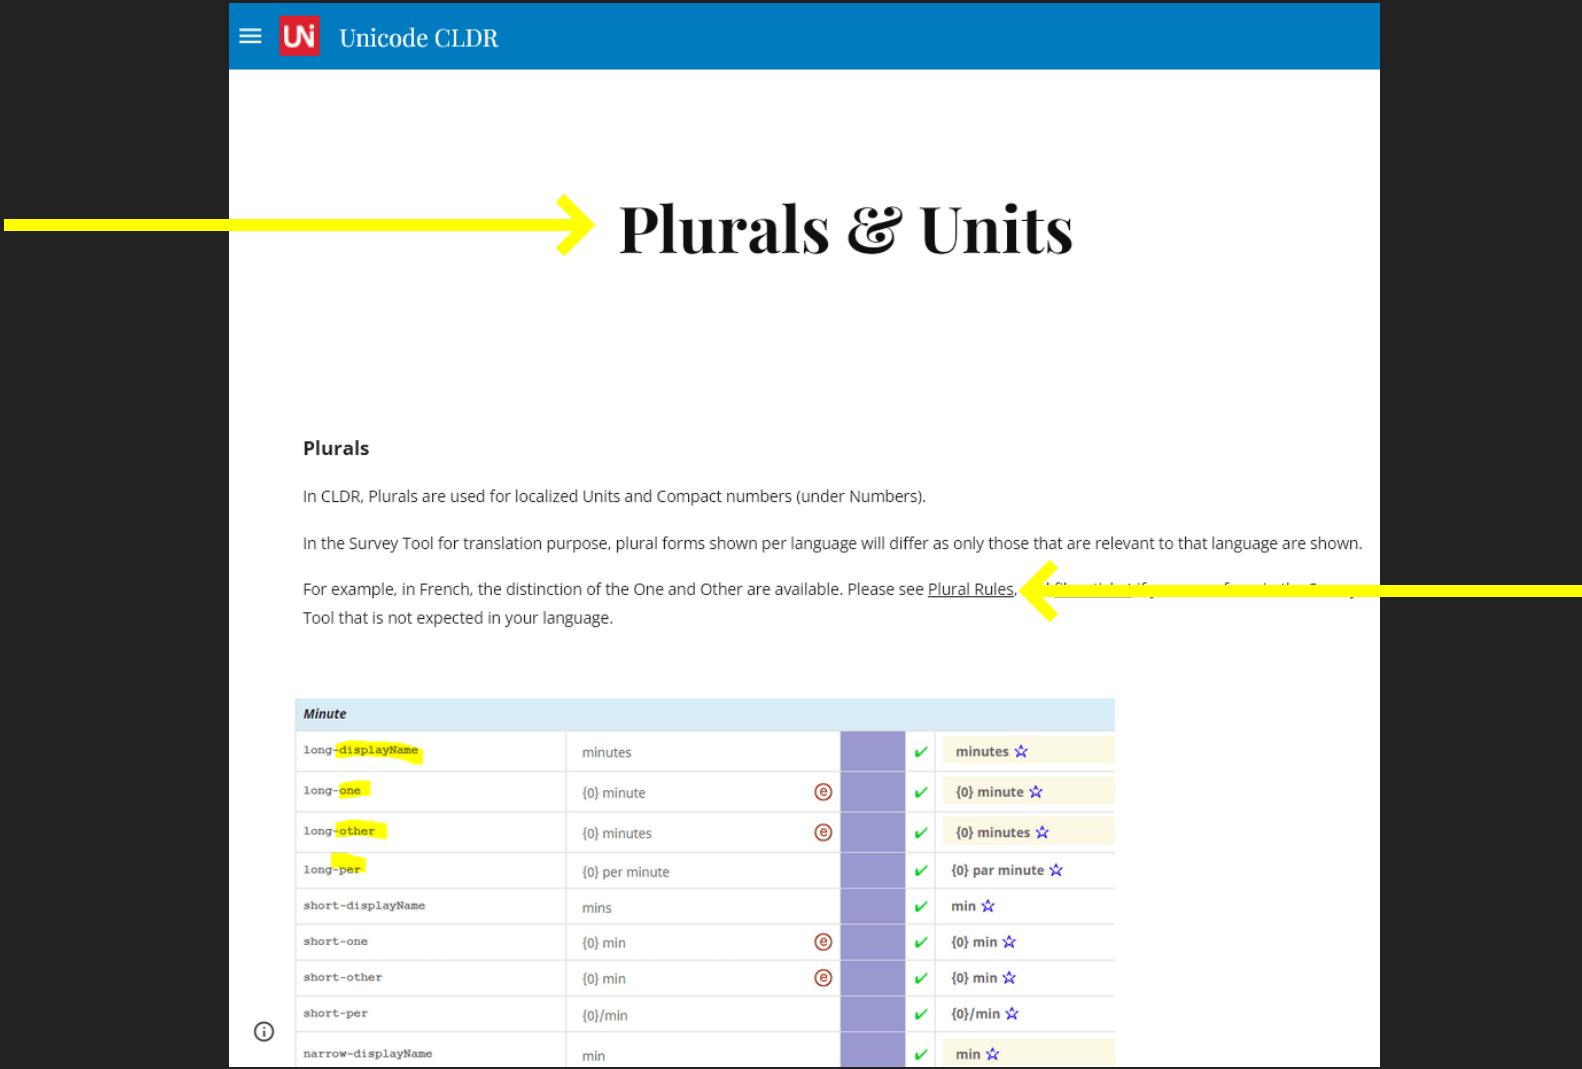

UNICODE

Unicode covers more than glyphs, code points, and their encodings!

CLDR

The CLDR defines machine readable rules for e.g. translation

Plurals & Units

Plurals

In CLDR, Plurals are used for localized Units and Compact numbers (under Numbers).

In the Survey Tool for translation purpose, plural forms shown per language will differ as only those that are relevant to that language are shown.

For example, in French, the distinction of the One and Other are available. Please see [Plural Rules](#).

Minute	
long-displayName	minutes
long-one	{0} minute
long-other	{0} minutes
long-per	{0} per minute
short-displayName	mins
short-one	{0} min
short-other	{0} min
short-per	{0}/min
narrow-displayName	min

CLDR v45.0 Language Plural Rules 2024-04-16

Index

Languages vary in how they handle plurals of nouns or unit expressions ("hours", "meters", and so on). Some languages have two forms, like English; some languages have only a single form; and some languages have multiple forms (see [Slovenian](#) below). They also vary between cardinals (such as 1, 2, or 3) and ordinals (such as 1st, 2nd, or 3rd), and in ranges of cardinals (such as "1-2", used in expressions like "1-2 meters long"). CLDR uses short, mnemonic tags for these plural categories. For more information on these categories, see [Plural Rules](#).

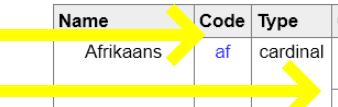

- **Examples:** The symbol ~ (as in "1.7~2.1") has a special meaning: it is a range of numbers that includes the end points (1.7 and 2.1), and everything between that has exactly the same number of decimals as the end points (thus also 1.8, 1.9, and 2.0, but not 2 or 1.91 or 1.90). The samples are generated mechanically, and are not comprehensive: "0, 2~19, 101~119, ..." could show up as the less-complete "0, 2~16, 101 ...".
- **Rules:** The plural categories are computed based on machine-readable rules, using the syntax described in [Language Plural Rules](#). In particular, they use special variables and relation defined in [Plural Rule Operands](#) and following.
- **Reporting Defects:** When you find errors or omissions in this data, please report the information with a [bug report](#). But first read "Reporting Defects" on [Plural Rules](#).

PLURAL FORMS

GNU **gettext** tries to cover many of these patterns in **single-line C expressions**.

Most **implementations** follow the **CLDR rules** because they cover more languages.

```
1 "Language: ja"
2 "Plural-Forms: nplurals=1; plural=0;"  
3
4 "Language: de"
5 "Plural-Forms: nplurals=2; plural=(n != 1);"  
6
7 "Language: cs"
8 "Plural-Forms: nplurals=3; plural=(n==1 ? 0 : n>=2 && n<=4 ? 1 : 2);"  
9
10 "Language: br"
11 "Plural-Forms: nplurals=5; plural=(n%10==1 && n%100!=11 && n%100!=71 && n%100!=91 ? 0 : n%10==2 && n%100!=12 &&
n%100!=72 && n%100!=92 ? 1 : ((n%10>=3 && n%10<=4) || n%10==9) && (n%100<10 || n%100>19) && (n%100<70 || n%100>79)
&& (n%100<90 || n%100>99) ? 2 : n!=0 && n%1000000==0 ? 3 : 4);"
```

BOOST.LOCALE

Among other things, it implements the **message** facet of std::locale

```
template <typename Char>
class basic_message {
    lots of constructors ...
    lots of conversions ...
    lots of write operations to streams ...
    ...
private:
    lots of translation and character encoding operations ...

    basic_string_view<Char> Singular;
    basic_string_view<Char> Plural;
    basic_string_view<Char> Context;
    long long                Cardinal;
};

lots of free function that create instances of basic_message
- translate( ... )
- gettext(), ngettext(), dgettext(), dngettext(), pgettext(), dpgettext()
```

brings additional **overloads** and **helpers** for Boost.Format

BOOST.LOCALE

it does too much!

every return operation

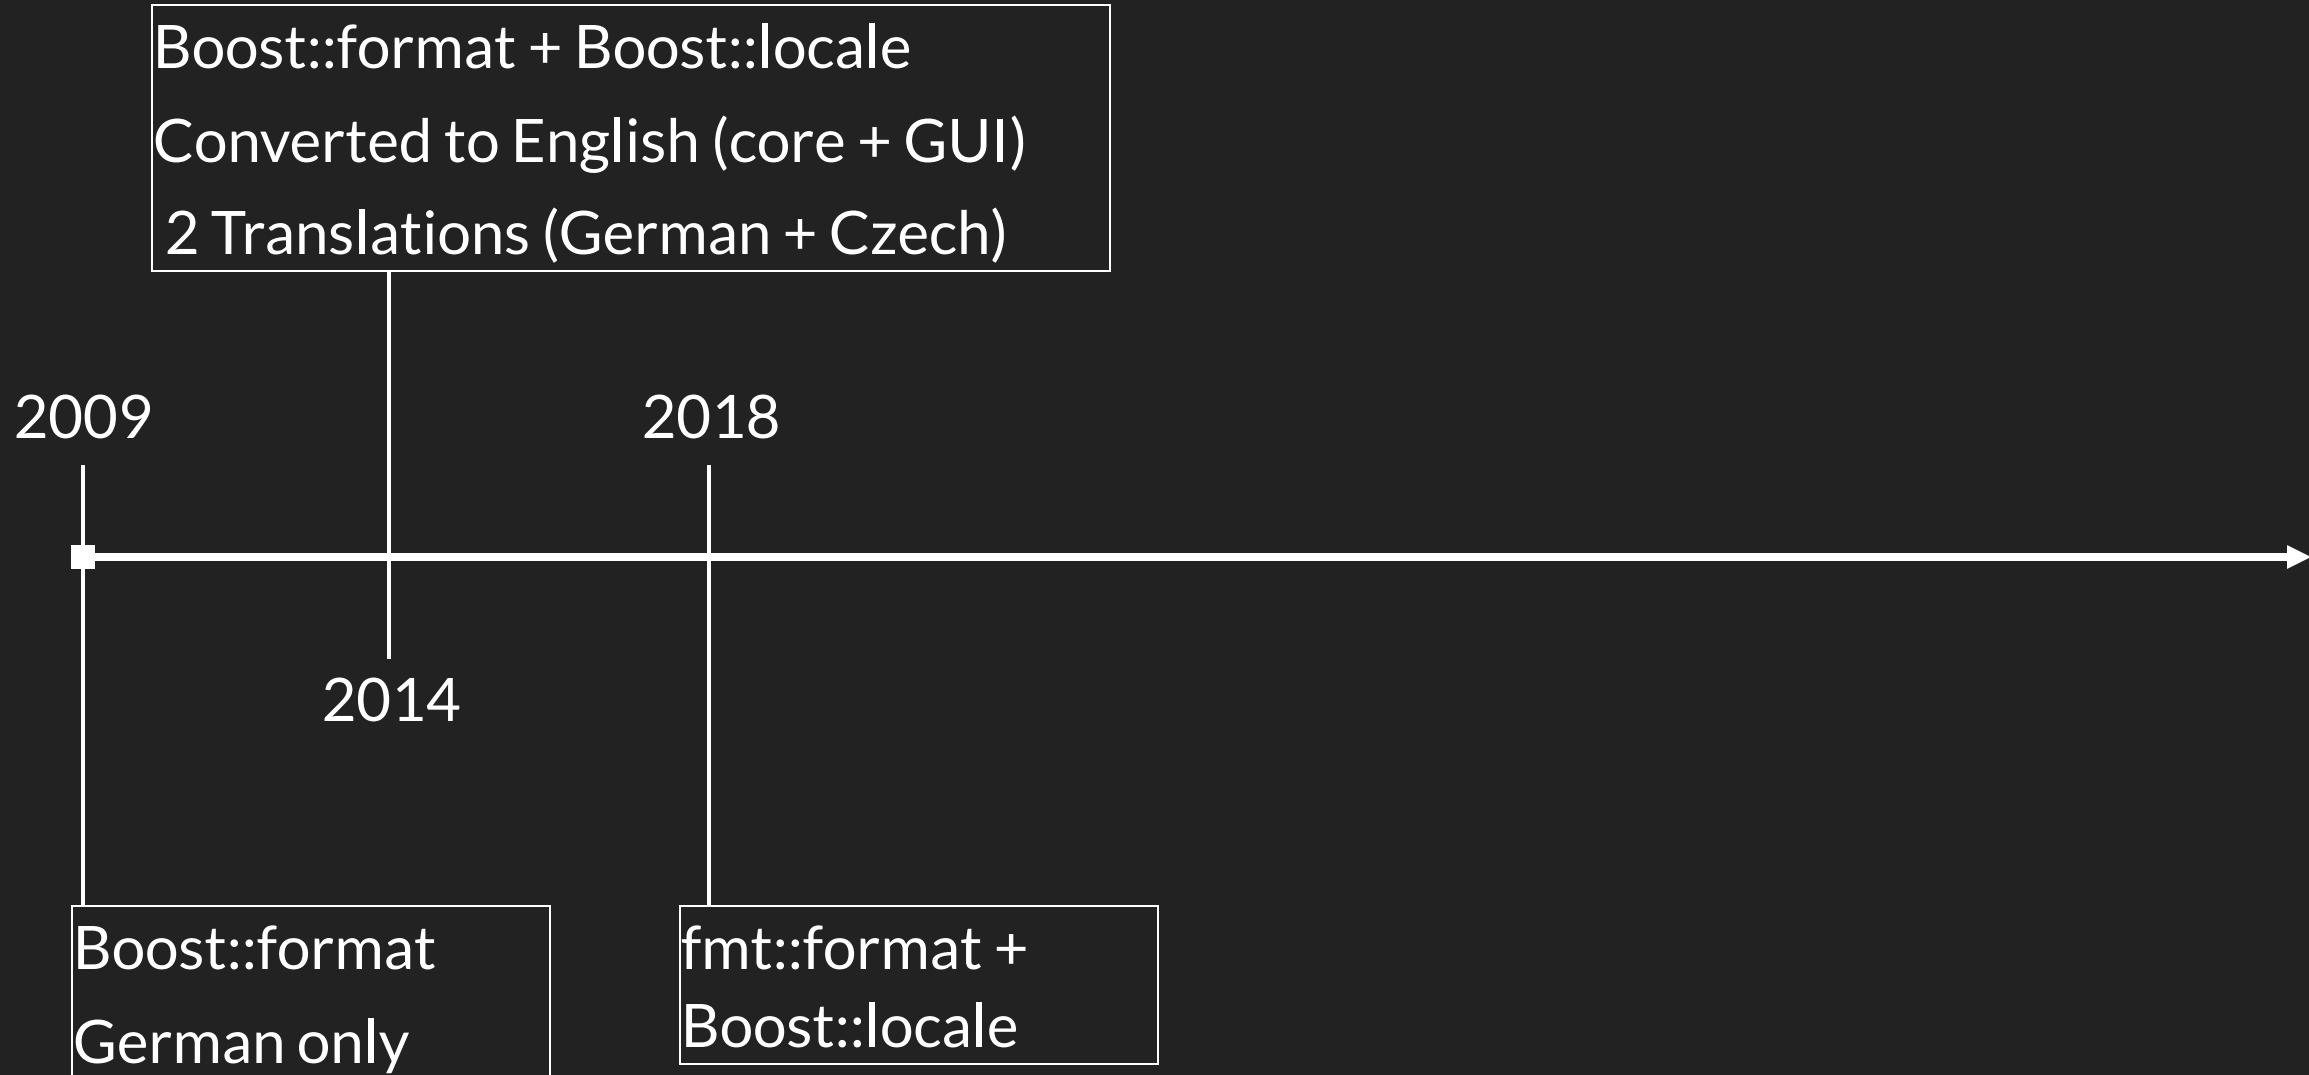

- does a translation
- does an encoding conversion

therefore it requires a string allocation

a new library

TIMELINE

{FMT}

```
#include <boost/format.hpp>

std::cout << boost::format("formatting specifier") % argument1 % argument2;
```

```
#include <fmt/format.hpp>

std::cout << fmt::format("formatting specifier", argument1, argument2);
```

```
1 template <typename Ch>
2 format(const something-related-to-Ch & FS) -> boost::basic_format<Ch>;
3     +
4 template <typename Ch, typename T>
5 operator%(boost::basic_format<Char> &, const T &) -> boost::basic_format<Ch>;
6
7 vs.
8
9 template <typename T1, typename T2>
10 format(std::string_view FS, T1 && Arg1, T2 && Arg2) -> std::string;
11
12 template <typename T1, typename T2>
13 format(std::wstring_view FS, T1 && Arg1, T2 && Arg2) -> std::wstring;
```

{FMT} HAS TWO INTERFACES!

```
1 #include <fmt/format.hpp>
2
3 // Interface 1
4
5 template <typename... Types>
6 format(std::string_view FS, Types &&... Args) -> std::string;
7
8
9 // Interface 2
10
11 vformat(std::string_view FS, format_args FA) -> std::string;
12
13
14 // Express interface 1 in terms of interface 2
15
16 template <typename... Types>
17 format(std::string_view FS, Types &&... Args -> std::string {
18     return vformat(FS, make_format_args(Args));
19 }
20 +
21 template <typename Context = format_context, typename... Args>
22 make_format_args(const Args &... args) -> format_arg_store <Context, Args...>;
```

TYPE ERASURE

```
1 // Typeful interface
2
3 template <typename... Types>
4 format(std::string_view, Types &&... Args) -> std::string;
5
6
7 // Type-erased interface
8
9 vformat(std::string_view, format_args) -> std::string;
10
11
12 // the type-full interface is a thin wrapper around the type-erased interface
13
14 template <typename... Types>
15 format(std::string_view FS, Types &&... Args -> std::string {
16     return vformat(FS, make_format_args(Args));
17 }
```

Type erasure, or better: **type classification**

TYPE ERASURE

```
#include <boost/format.hpp>

template <typename Ch>
format(const something-related-to-Ch &) -> boost::basic_format<Ch>;
```

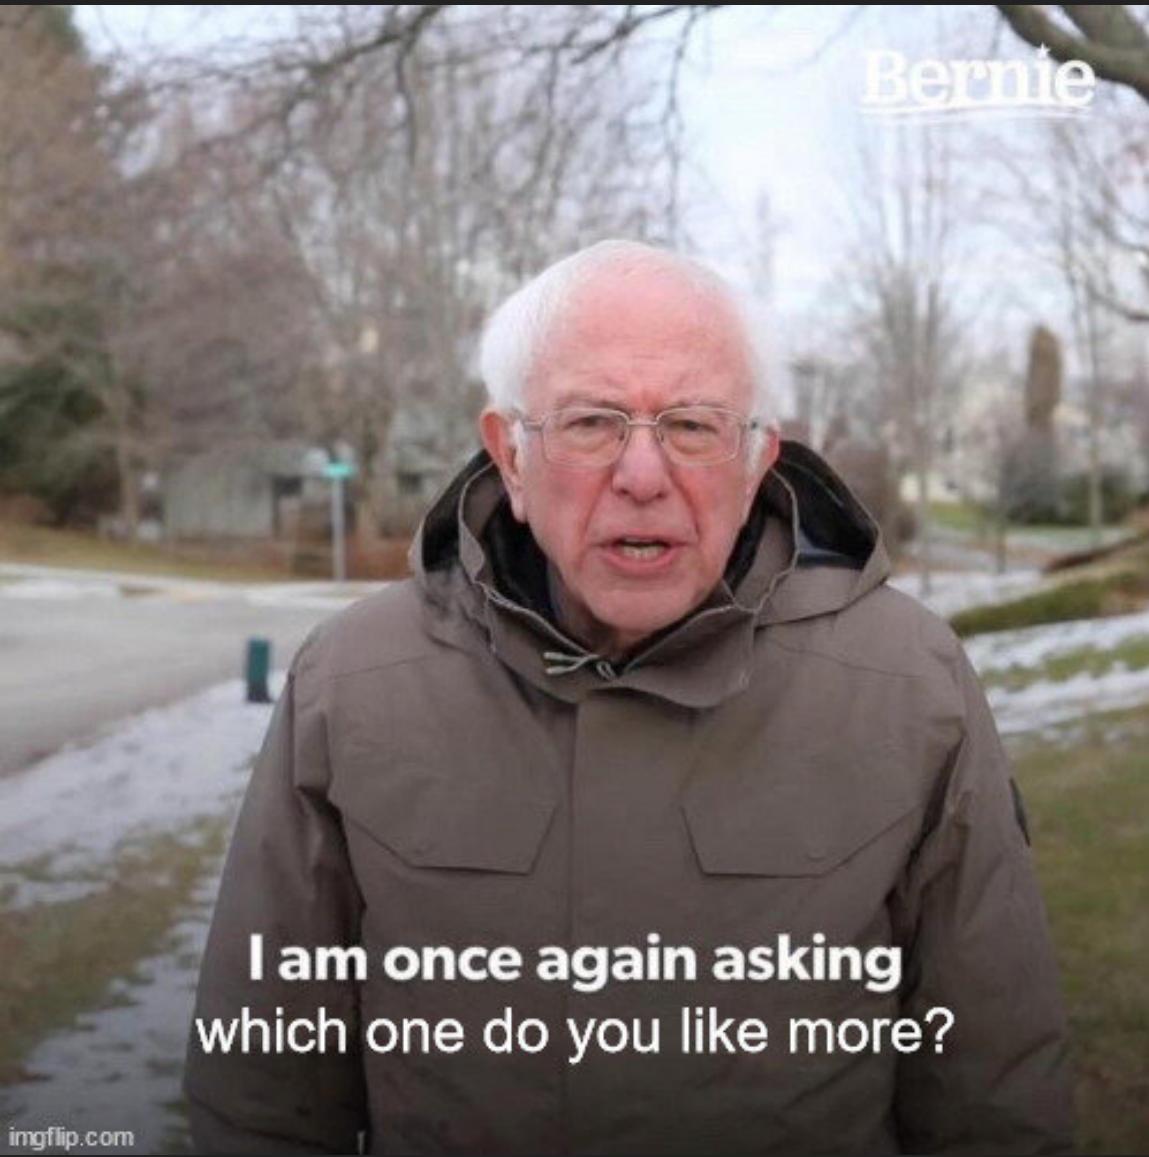

```
template <typename Ch, typename Traits, typename Allocator>
class basic_format {
    ...
    template <typename T>
    operator%(const T &) -> basic_format;
    ...

private:
    ...
    std::vector<format_item_t> items_; // each '%' directive leads to a format_item
    ...
};
```

Type erasure

CHOICES...

Ficticiously replace 'operator%()' with 'operator,()'

```
#include <boost/format.hpp>

format("formatting specifier"), argument1, argument2;
```

```
#include <fmt/format.hpp>

format("formatting specifier", argument1, argument2);
```

TYPE ERASURE

{fmt} is using all kinds of **type-based** metaprogramming to achieve its goals:

- **templates** (type calculations)
- **partial template specializations** (i.e. "pattern matching")
- **overload** resolution and implicit **conversion** sequences of unimplemented functions (conversion-based metaprogramming)
- **SFINAE** ("substitution failure is not an error") to control overload sets and viability of functions

RULE OF Chiel Douwes ❤

COST OF OPERATIONS

- SFNAE
- Instantiating a function template
- Instantiating a type
- Calling an alias
- Adding a parameter to a type
- Adding a parameter to an alias call
- looking up a memoized type^I

AKA THE RULE OF CHIEL

WHAT IS A FUNCTION?

for every x from the definition domain,
there is a y from the value domain, with

$$\text{let } y = f(x)$$

$$x \rightarrow y$$

x can be from any domain,
so does y , it can be from a different domain

WHAT IS A FUNCTION?

the operator f describes any kind of mapping

anything,

not necessarily just
one element

$$f: x \rightarrow \begin{cases} y_0 & \text{if } x \text{ matches predicate 0} \\ y_1 & \text{if } x \text{ matches predicate 1} \\ y_2 & \text{if } x \text{ matches predicate 2} \end{cases}$$

anything else,

necessarily exactly
one element

WHAT IS A FUNCTION?

operator f may have **any** number of arguments with a **definite** number of return values

$f()$	✓	$f()$	$\rightarrow (y_0, y_1, y_2, \dots)$	✗
$f(x)$	✓	$f(x)$	$\rightarrow (y)$	✓
$f(x_0, x_1)$	✓	$f(x_0, x_1)$	$\rightarrow ()$	✓
$f(x_0, x_1, x_2)$	✓	$f(x_0, x_1, x_2)$	$\rightarrow (...)$	✗
$f(x_0, x_1, x_2, \dots)$	✓	$f(x_0, x_1, x_2, \dots)$	$\rightarrow (y_0, y_1, y_2)$	✓
$f(...)$	✓	$f(...)$	$\rightarrow (y_0, y_1)$	✓

WHAT IS A FUNCTION?

names are **unimportant** as long as they are **unique**

f()

g()

h()

ařnt_Ařňiž() ✓

()

some unutterable name

WHAT IS A FUNCTION?

spellings are **unimportant**, but they may have **context**

$y = f(x)$  $x \rightarrow y$

$y = f\{x\}$  $x \rightarrow y$

$y = f[x]$  $x \rightarrow y$

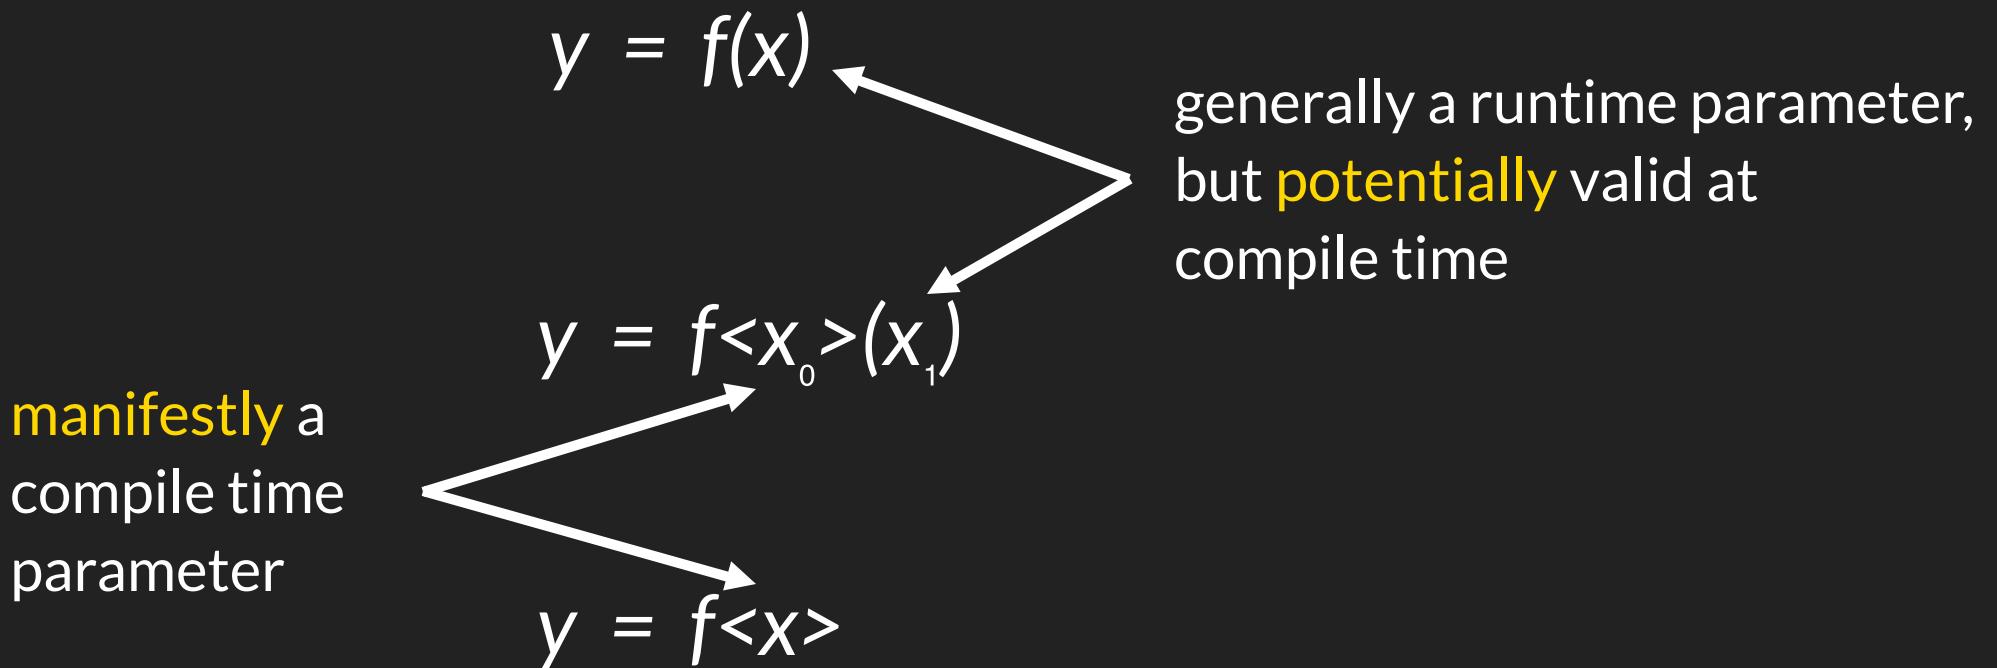

$y = f\langle X \rangle$  $x \rightarrow y$

$y = f\langle x \rangle$  $x \rightarrow y$

$y = f\langle x_0 \rangle(x_1)$  $x_0, x_1 \rightarrow y$

WHAT IS A FUNCTION?

the **context** is important, in which parameters are **valid**

WHAT IS A FUNCTION?

functions can return any number of things of any kind

$$y = f<x>$$

$$y = f<x_0, x_1, \dots>$$

x: type parameter, non-type parameter (integral, pointer, reference, enumerations, classes, templates, placeholders)

see <http://eel.is/c++draft/temp.param> and <http://eel.is/c++draft/temp.arg>

y: pretty much any C++ object, reference, and alias that you can e.g. use as class member, but also values

WHAT IS A FUNCTION?

the **type traits** from the standard library are your friend

<i>std::is_object<T></i>	✓	$T \rightarrow \text{bool}$
<i>std::is_convertible<From, To></i>	✓	$T_0, T_1 \rightarrow \text{bool}$
<i>std::remove_cvref<T></i>	✓	$T \rightarrow T'$
<i>std::common_type<T₀, T₁></i>	✓	$T_0, T_1 \rightarrow U$
<i>std::invoke_result<f<Ts...>></i>	✓	$f, Ts... \rightarrow U$
<i>std::void_t<Ts...></i>	✓	$Ts... \rightarrow \text{void}$
<i>std::vector<T></i>	✓	$U, T \rightarrow V$

WHAT IS A FUNCTION?

there are **multiple** ways to say the same

<code>template<T></code>		
<code>struct S { enum bool { value = ...}; };</code>	✓	$T \rightarrow \text{bool}$
<code>template<T></code>		
<code>constexpr bool value = ...;</code>	✓	$T \rightarrow \text{bool}$
<code>template<T></code>		
<code>std::bool_constant value(T) noexcept { ... };</code>	✓	$T \rightarrow \text{bool}$

ONCE MORE...

COST OF OPERATIONS

- SFNAE
- Instantiating a function template
- Instantiating a type
- Calling an alias
- Adding a parameter to a type
- Adding a parameter to an alias call
- looking up a memoized type

AKA THE RULE OF CHIEL

Metal

use libraries!

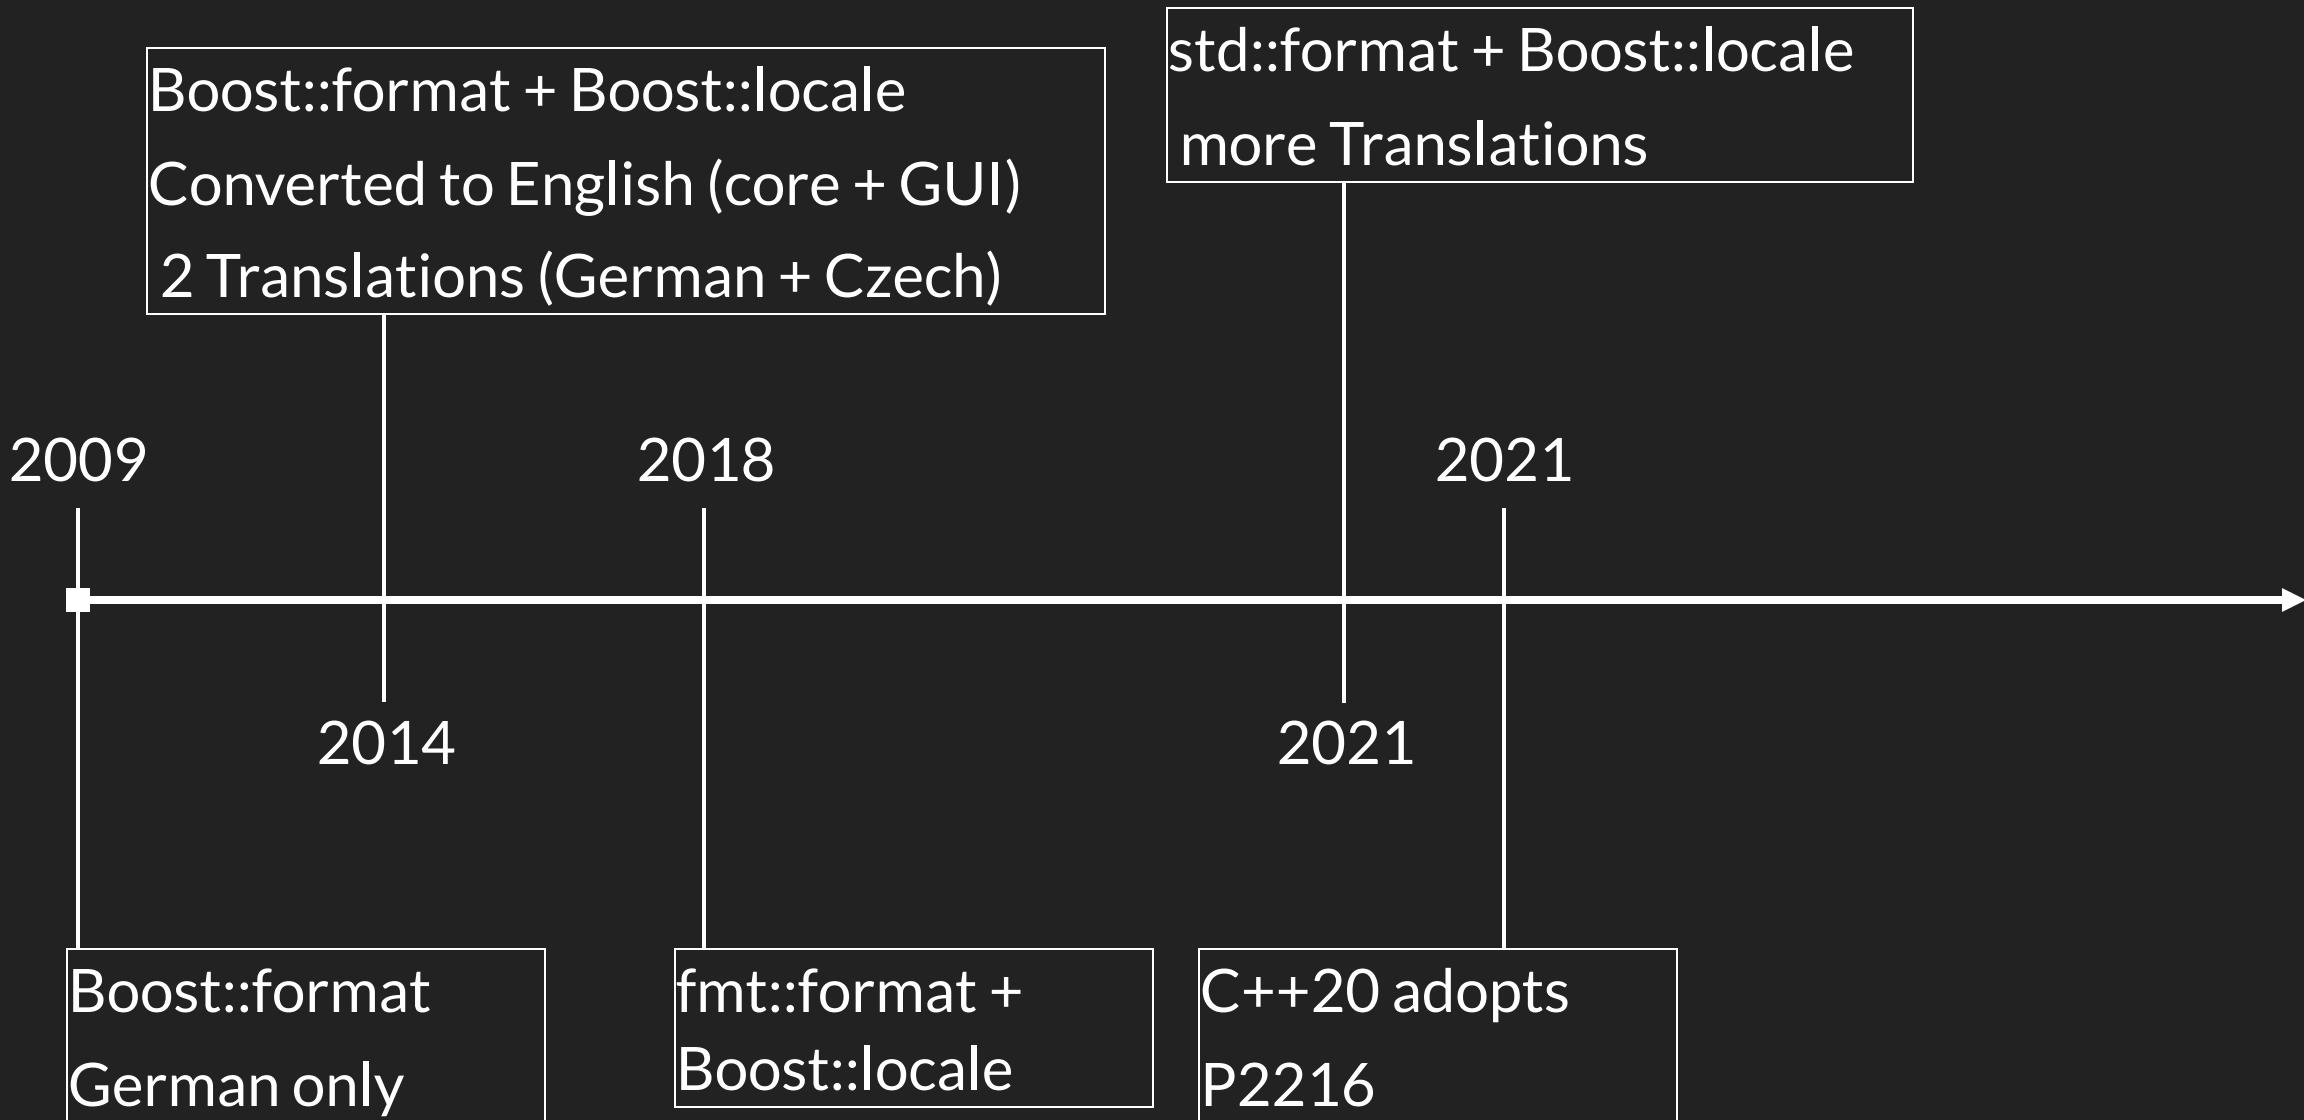

Kvasir

Brigand

a new world

TIMELINE

FROM C++20 TO C++20

Original C++20 (Prague 2020, N4860)

```
1 template<typename ... Types>
2 auto std::format(std::string_view Fmt, const Args &... Args) -> std::string {
3     return std::vformat(Fmt, std::make_format_args(Args ...));
4 }
```

Today's C++20 (April 2024, N4981)

```
1 template<typename ... Types>
2 auto std::format(std::format_string<Types...> Fmt, Args &&... Args) -> std::string {
3     return std::vformat(Fmt.get(), std::make_format_args(Args ...));
4 }
5
6 template <typename ... Types>
7 struct format_string {
8     consteval format_string(std::string_view Str) : Str_(Str) {}
9
10    constexpr std::string_view get() const noexcept { return Str_; }
11
12 private:
13     std::string_view Str_;
14 };
```

CONSTEVAL

P2216

2020:

- the `std::string_view` was **potentially** evaluated (and constructed) at compile time
- in **most** cases compile time evaluation succeeds

2021:

- the `std::format_string` is **necessarily** evaluated and constructed at compile time
- and so is the `std::string_view` that it is constructed from
- the arguments to the constructor of `std::string_view` **must** be known at compile-time!
- for more, please see <http://eel.is/c++draft/expr.const#16>

P2216

```
1 template<typename... Types>
2 auto std::format(std::format_string<Types...> Fmt, Args &&...) -> std::string {}
3
4 template <typename... Types>
5 struct format_string {
6     consteval format_string(std::string_view Str) : {
7         constexpr size_t num_args = sizeof...(Types);
8         constexpr basic_format_arg_type arg_types[num_args > 0 ? num_args : 1] = {
9             std::get_format_arg_type<Types>()...
10        };
11
12        parse_format_string(Str, format_checker<std::remove_cvref_t<Types>...>{Str, arg_types});
13    }
14};
```

format string **syntax** and argument **type** checking can - and will - be done
at compile time
no more exceptions at runtime!

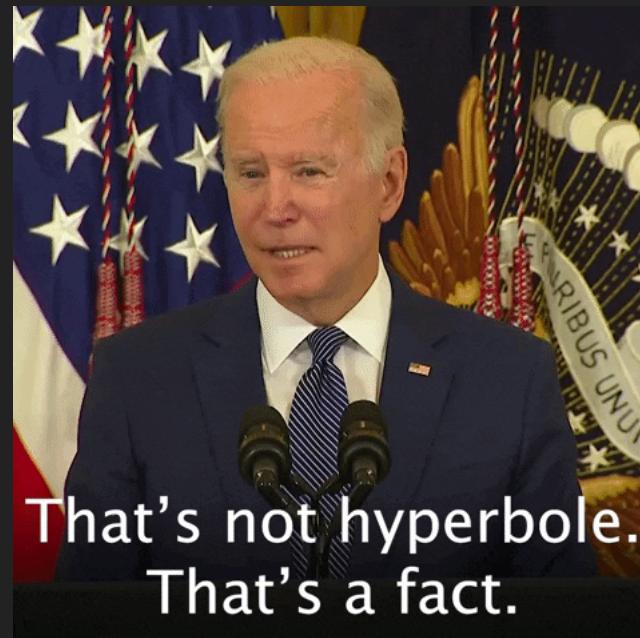

WHAT IS CONSTANT EVALUATION?

During compilation, the compiler has to remember everything it has seen so far:

- identifiers
- entities
- declarations
- definitions
- ...
- templates
- all template instantiations so far

Pretty much everything.

BTW, this is why we have modules now 

WHAT IS CONSTANT EVALUATION?

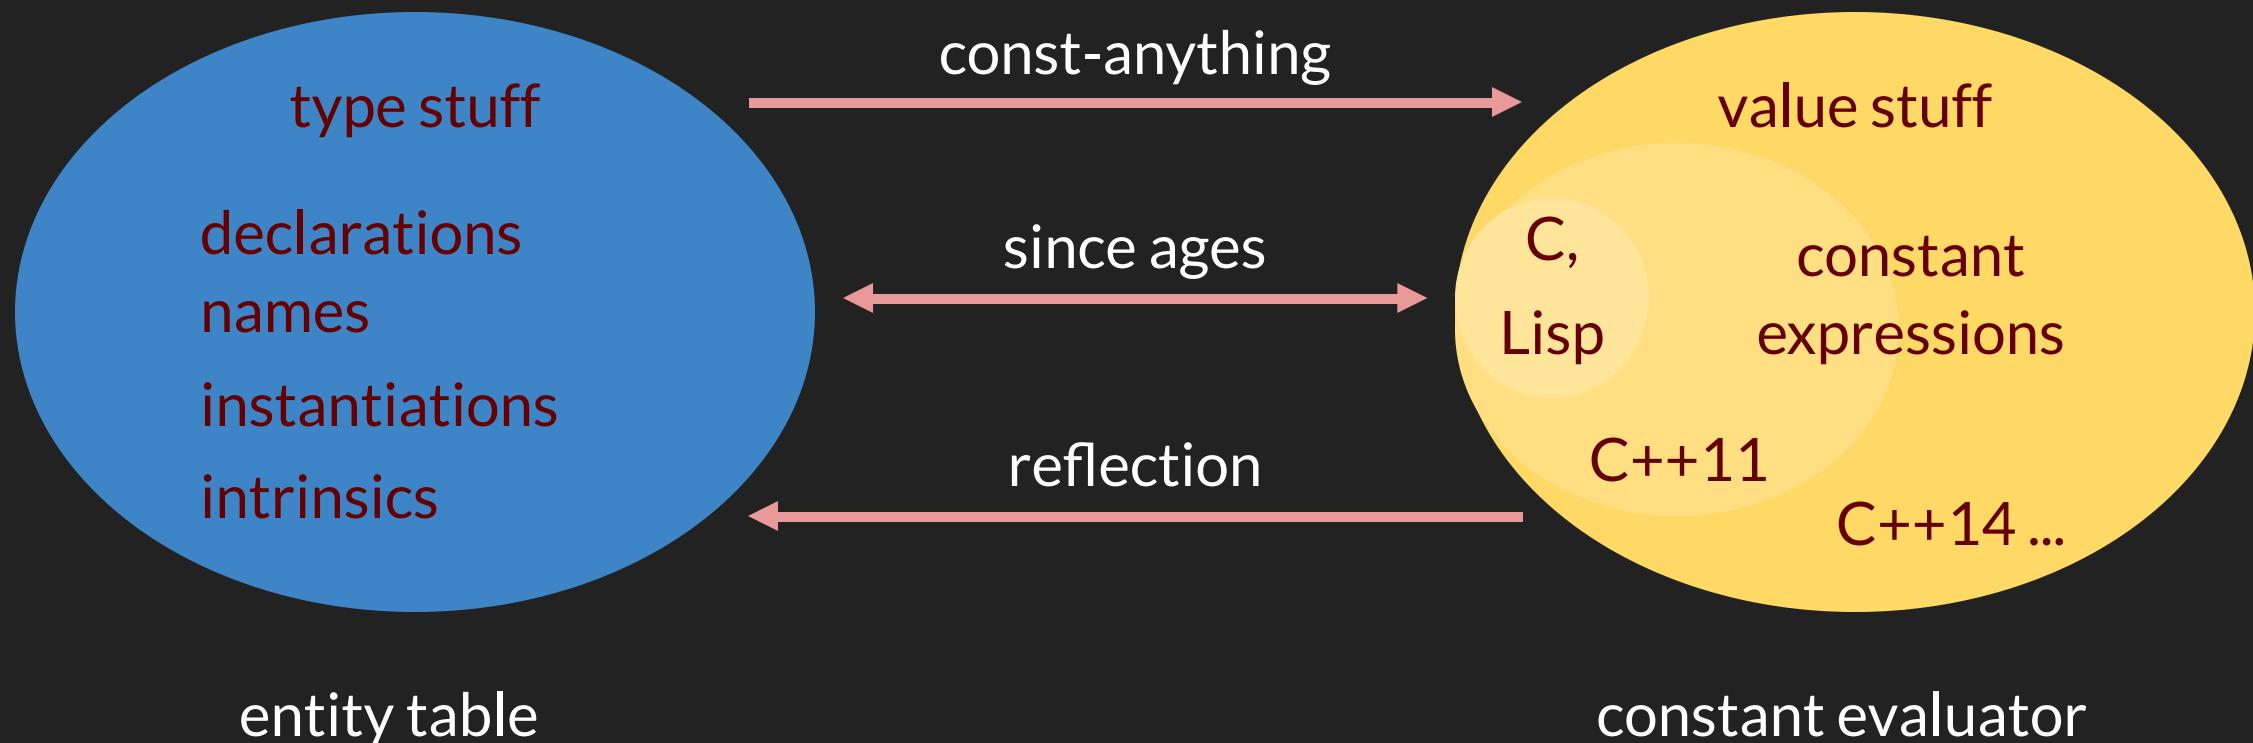

But what about those?

- `int i = 1 + 2 + ¾;`
- `bool b{ 42 == L"42" };`
- `char a[] = "huh?";`
- `enum e { none, anyone, couple };`
- `static_assert(none != anyone);`
- `const int c = couple;`
- `std::vector v = { none * 2, anyone * sizeof(a), couple * c };`
- ...

constant required,
"constant expression"

SPLIT BRAIN

There are actually two subsystems in the compiler that handle compile-time entities

CONSTANT EXPRESSION

Wherever a "constant" is required , a

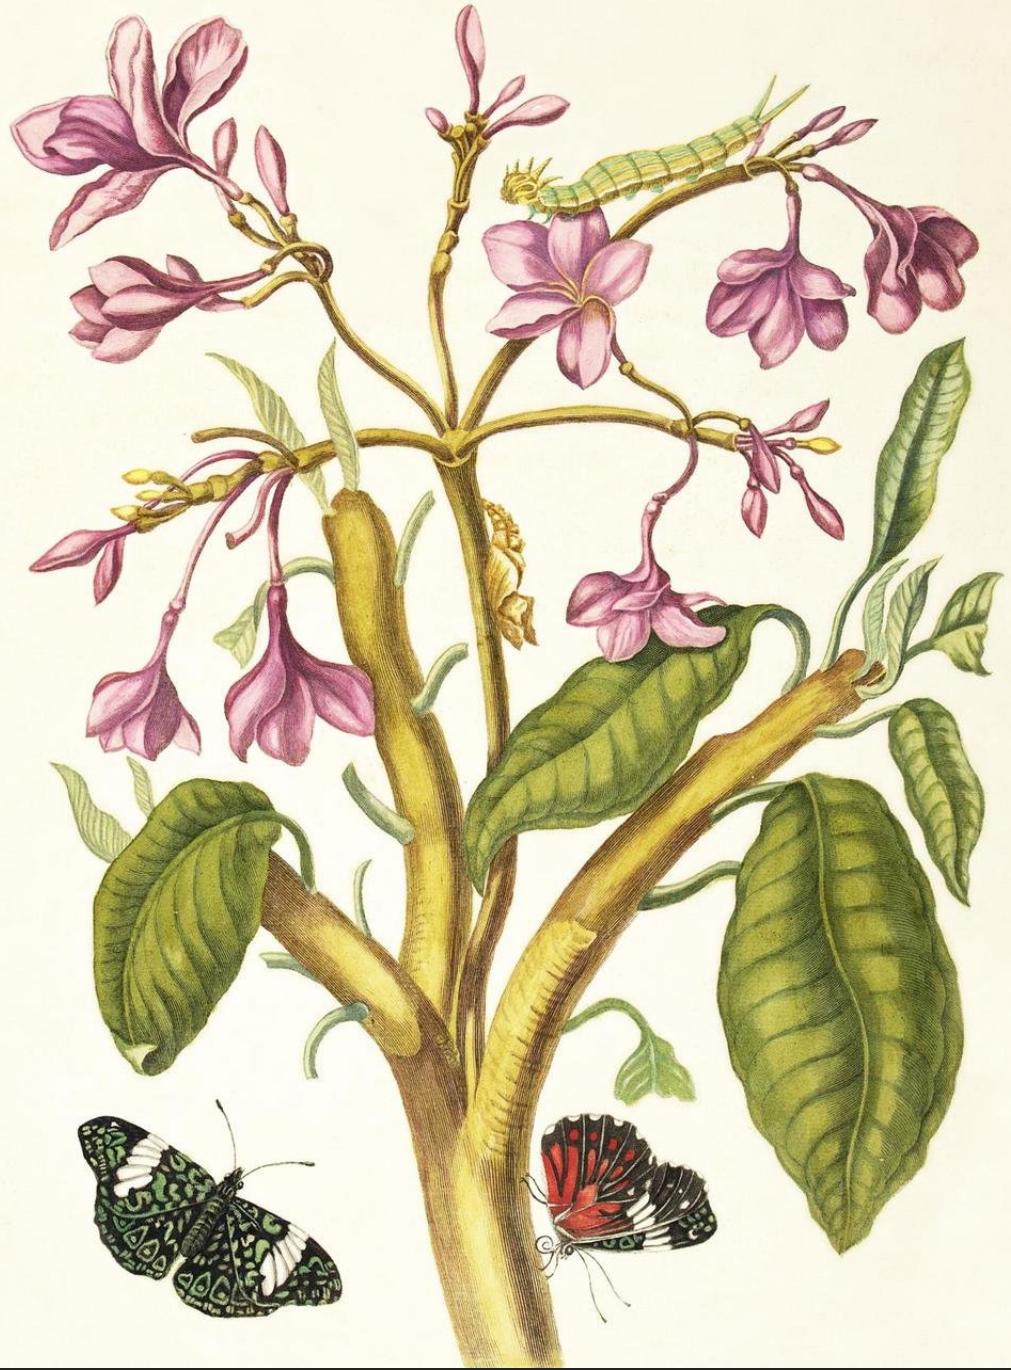

new constant evaluation

is started

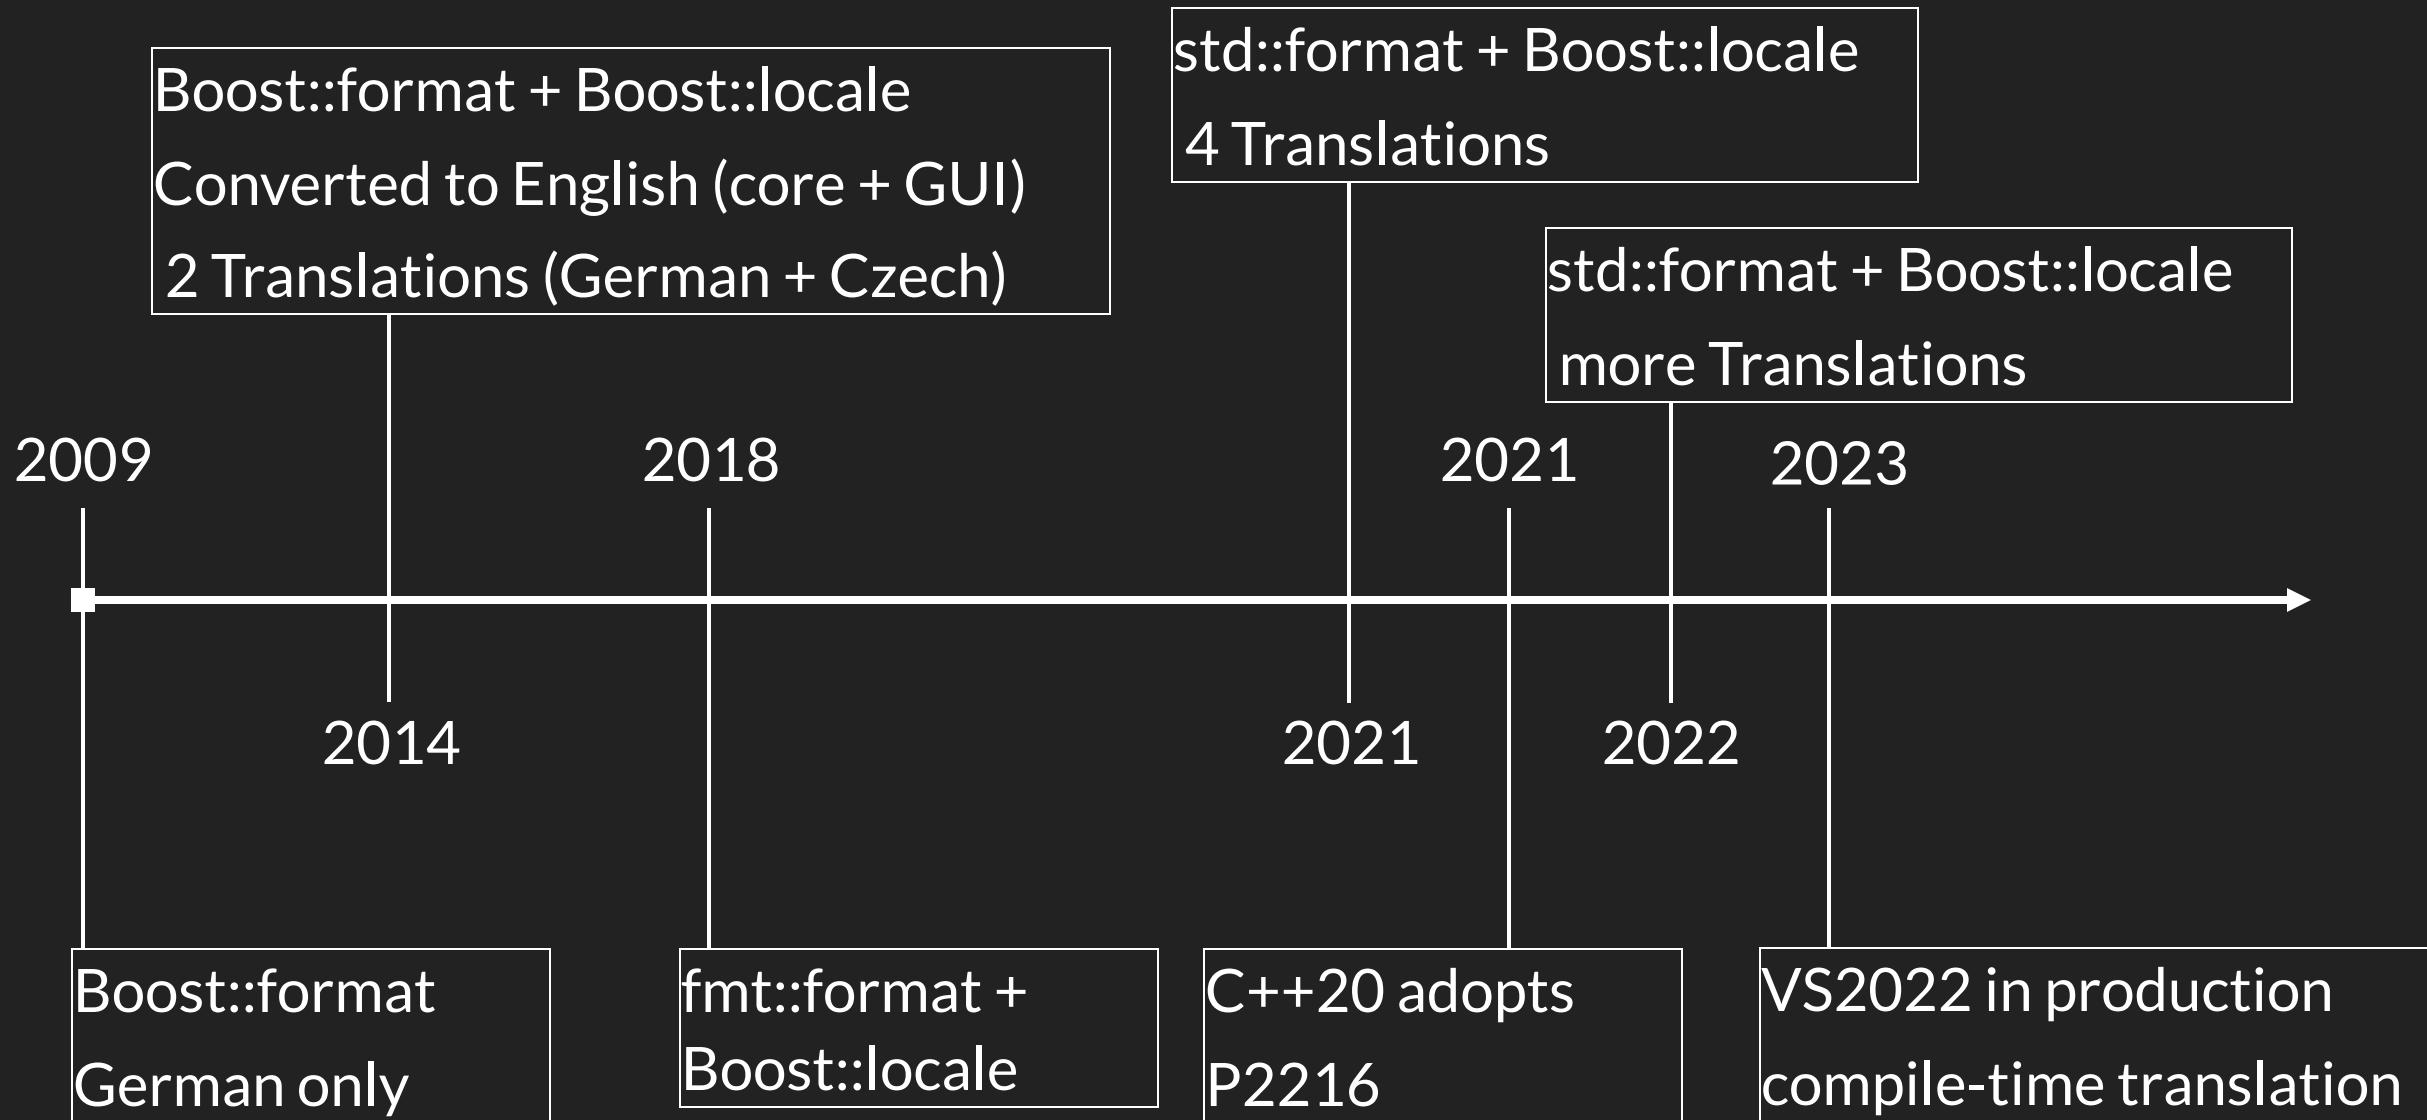

even if you are **already**
within a constant evaluation!

what now?

TIMELINE

P2216 FALLOUT

~~Boost::locale~~

at least,
the translation **frontend** with
runtime translation is no longer a thing

WHAT NOW?

a closer look

```
1 struct format_string {
2     consteval
3     format_string(const convertible_to<std::string_view> & Str) : Str_(Str) {}
4
5     constexpr
6     std::string_view get() const noexcept { return Str_; }
7 };
```

MO' OVERLOADS

```
1 template <typename... Types>
2 auto format(const format_string_translator<Types...> XFmt, Types &&... Args) -> std::string {
3     if constexpr (sizeof...(Args) > 0) {
4         const auto Quantity = XFmt.Quantity( ... something with Args );
5         return std::vformat(XFmt.get(Quantity),
6                             make_format_args(
7                                 wrapped<std::remove_cvref_t<Types>>::translate(Args)...,
8                             )));
9     } else {
10         return std::vformat(XFmt.get(), {});
11     }
12 }
```

FORMAT_STRING_TRANSLATOR

```
1 template <typename... Types>
2 auto format(const format_string_translator<Types...>, Types &&...) -> std::string;
3
4 template <typename... Types>
5 struct format_string_translator : basic_translator {                                // empty class!
6     using base = format_string<Types...>;
7
8     static constexpr auto numPluralArguments = (isMarkedAsPlural<Types> + ... + 0);
9     static_assert(numPluralArguments <= 1, "Oops, more than one plural argument was found!");
10
11    consteval format_string_translator(const tTranslate & Tr)           // almost all work is done here
12        : basic_translator(Tr) {
13            base{ Tr.Singular() }, base{ Tr.Plural() }, checkPlural(Tr.lenPlural_, numPluralArguments);
14        }
15    };
16
17    consteval void checkPlural(std::size_t gotPluralFormat, std::size_t havePluralArguments) {
18        if (gotPluralFormat and not havePluralArguments)
19            throw "Sorry, a plural format string is present, but no plural argument was found!";
20        if (havePluralArguments and not gotPluralFormat)
21            throw "Sorry, a plural argument was found, but no plural format string is present!";
22    }
23
24 template <typename T>
25 constexpr bool isMarkedAsPlural = std::is_same_v<plural, T>;
```

BASIC_TRANSLATOR

```
1 template <typename... Types>
2 auto format(const format_string_translator<Types...>, Types &&...) -> std::string;
3
4 template <typename... Types>
5 struct format_string_translator : basic_translator { // knows argument types, does syntax checking
6
7     struct basic_translator { // knows only string digest, and how to translate from actual cardinal
8         consteval basic_translator(const tTranslate & Tr)
9             : Translator_{ markPluralsPresent(Tr.Digest_, Tr.lenPlural_ > 0) } {}
10
11     std::string_view get(plural::type N) const noexcept {
12         return havePlurals(Translator_.Digest_) ? Translator_.multiple(N) : Translator_.single();
13     }
14
15     std::string_view get() const noexcept { return Translator_.single(); }
16
17 private:
18     tBaseTranslate Translator_; // strips off all strings, knows only the digest
19 };
20
21 constexpr bool havePlurals(const uint64_t Digest) { ... }
22
23 consteval uint64_t markPluralsPresent(const uint64_t Digest, const bool havePlural) { ... }
```

BASIC_TRANSLATOR

```
1 template <typename... Types>
2 auto format(const format_string_translator<Types...>, Types &&...) -> std::string;
3
4 template <typename... Types>
5 struct format_string_translator : basic_translator; // knows argument types, does syntax checking
6
7 struct basic_translator {}; // knows only string digest, and how to translate from actual cardinal
8
9 struct tBaseTranslate {                                // perform translation from compile-time digest
10    constexpr auto single() const noexcept -> std::string_view {
11        const auto & Maps = ...;           // from backend;
12        return lookup(Maps, Digest_);     // middle: wed frontend and backend □
13    }
14
15    constexpr auto multiple(plural::type N) const noexcept -> std::string_view {
16        const auto & Maps = ...;           // from backend;
17        return lookup(Maps, Digest_, std::uint64_t{ N }); // middle: wed frontend and backend □
18    }
19
20    ... more overloads of 'single()' and 'multiple(N)'
21
22    std::uint64_t Digest_; // constructed by frontend at compile-time
23 };
```

the only
runtime code

3 QUESTIONS

```
1 template <typename... Types>
2 auto format(const format_string_translator<Types...> XFmt, Types &&... Args) -> std::string {
3     const auto Quantity = XFmt.Quantity( ... something with Args); 1, 2
4     return std::vformat(XFmt.get(Quantity),
5                         make_format_args(wrapped<std::remove_cvref_t<Types>>::translate(Args)...));
6 }
```

3

- 1 which argument holds the cardinal that determines the language form?
- 2 how to access its current value?
- 3 how to figure out how a given argument is translated? Or is it at all?

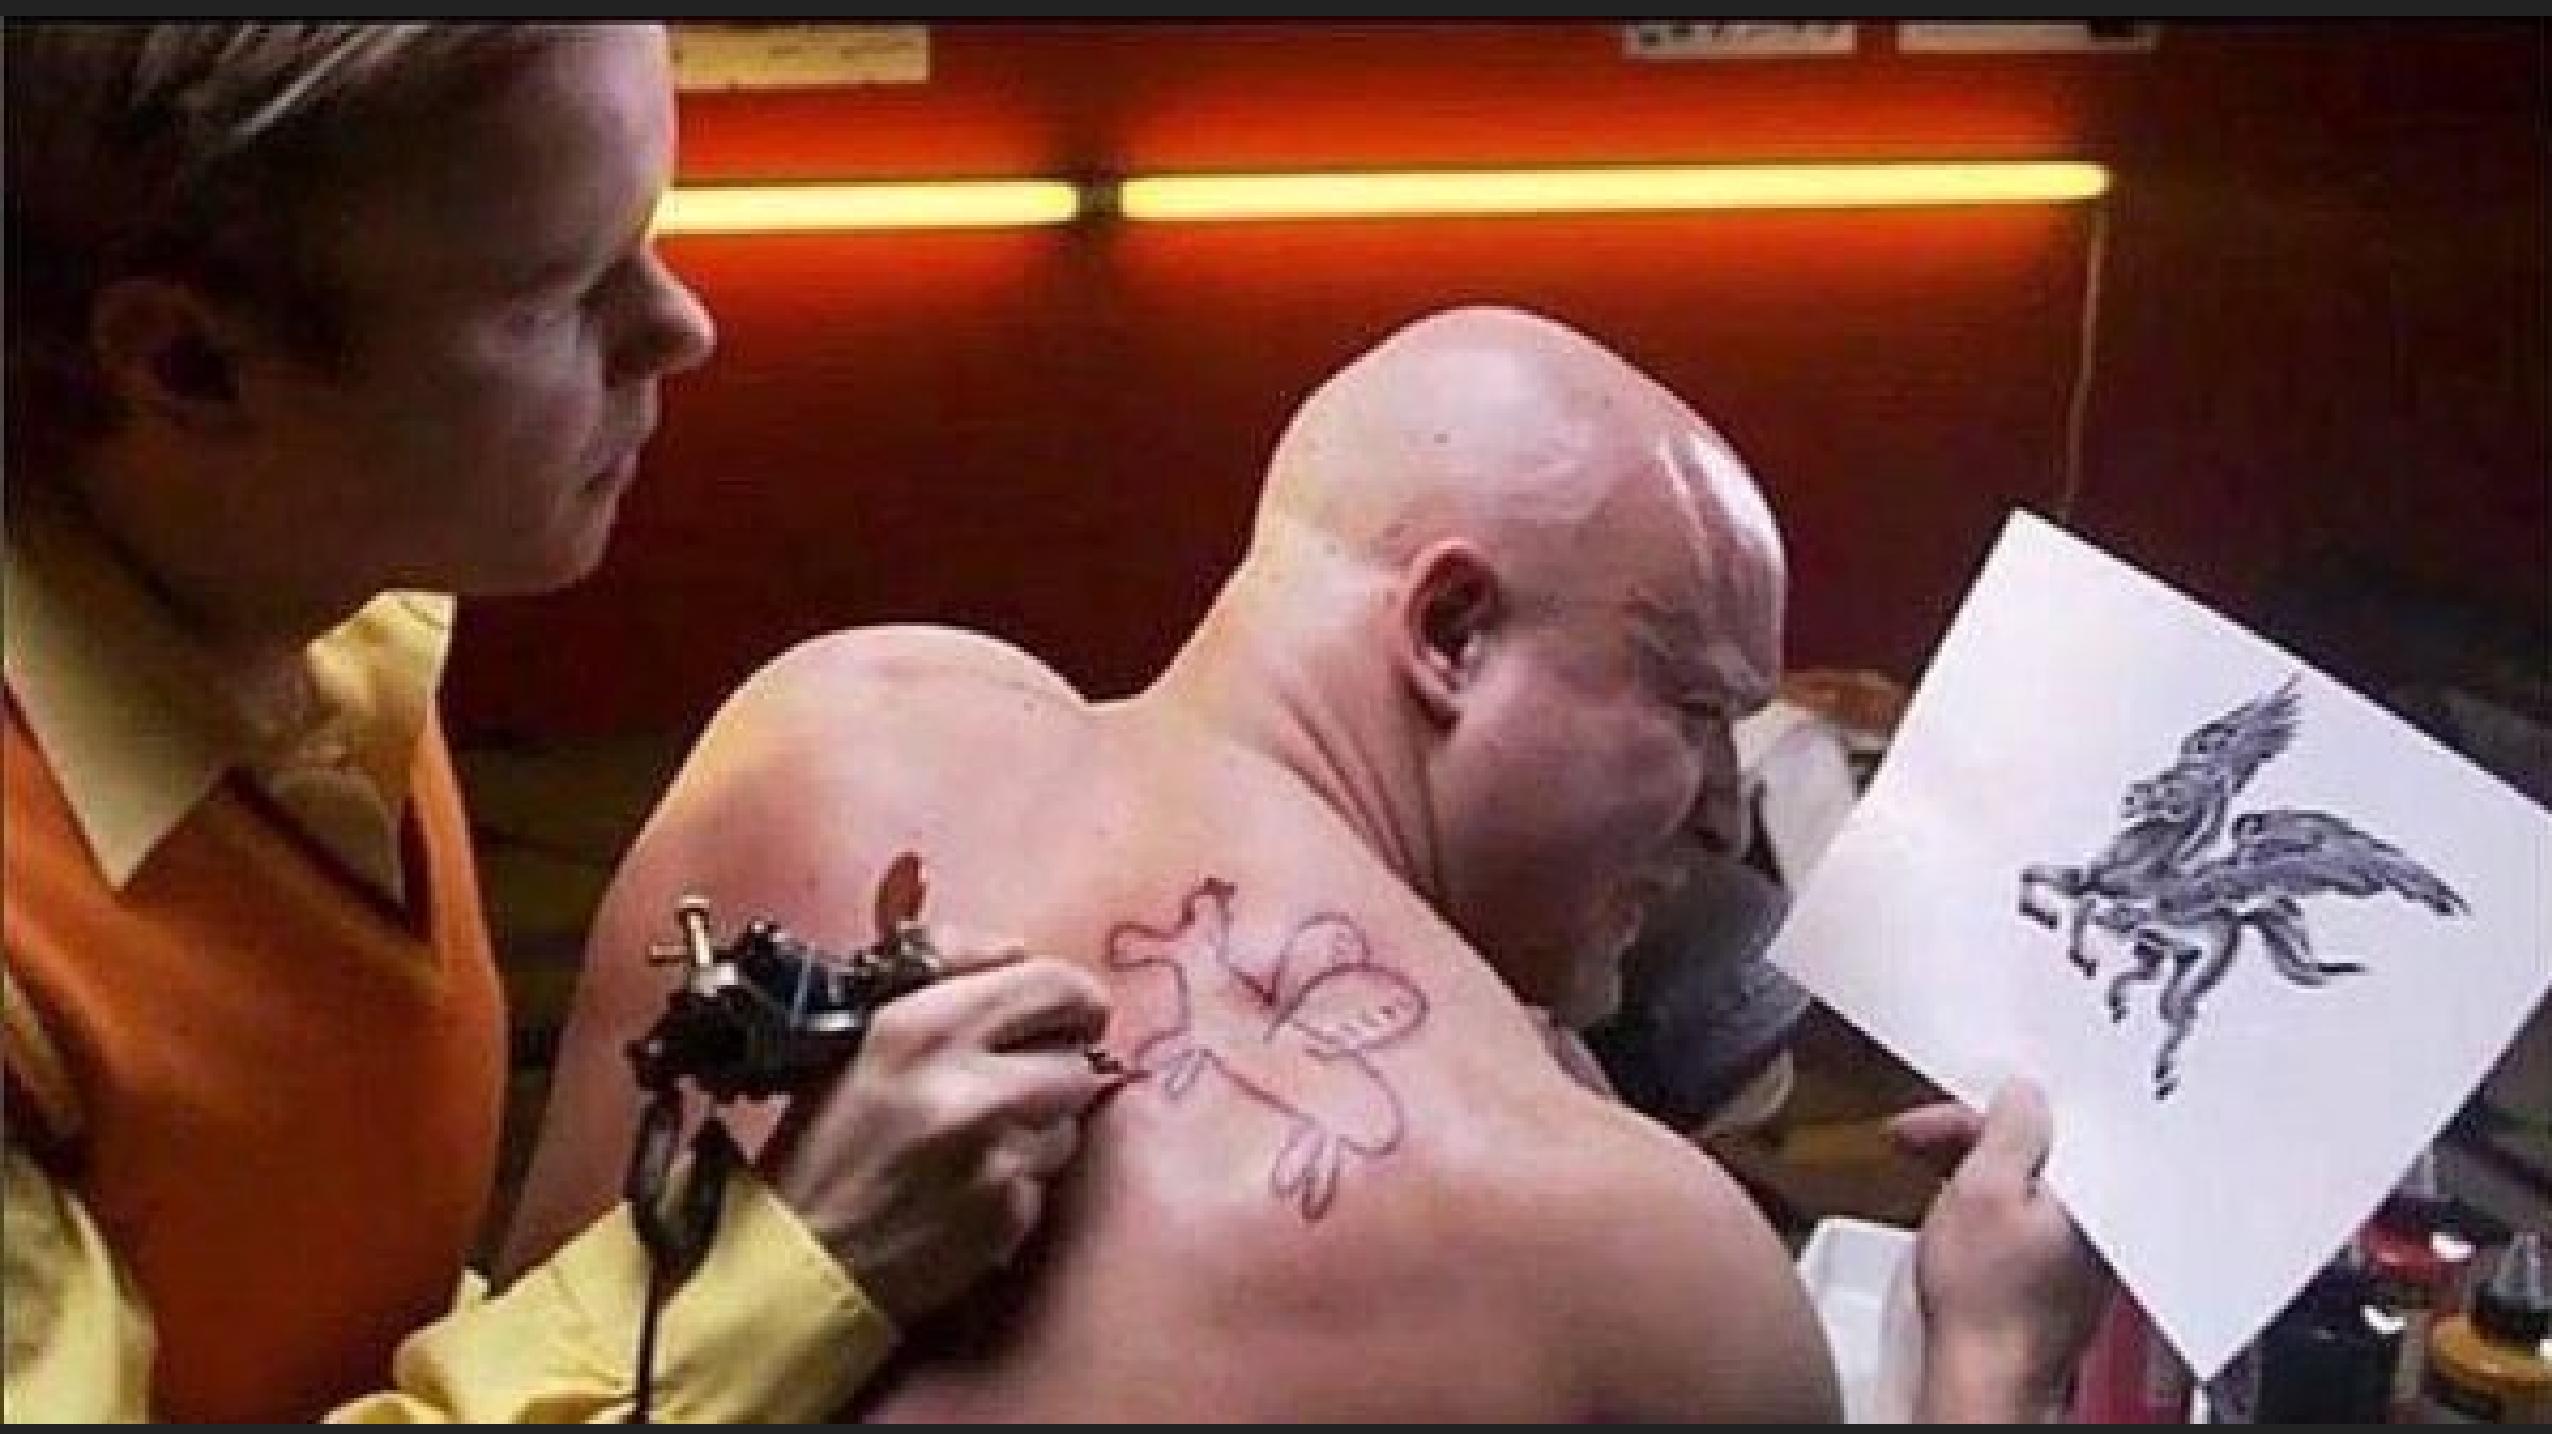

P2663 (PACK INDEXING) + P2996 (REFLECTION)

```
1 template <typename... Types>
2 auto format(const format_string_translator<Types...> XFmt, Types &&... Args) -> std::string {
3     constexpr auto Index = std::ranges::find_if({ Args^... }, isPluralType) - &Args...[0]^;
4     return std::vformat(XFmt.get(Args...[Index]), 2 1
5                         make_format_args( [... something with Args^... ...]));
6 }
```

3

- 1** which argument holds the cardinal that determines the language form?
- 2** how to access its current value?
- 3** how to figure out how a given type is translated? Or is it at all?

Unfortunately, this is 2024. C++26 is not a thing yet 😞

WHAT IS THE PLURAL INDEX?

For **homogenous** sequences you need two things:

- the proper **algorithm**, e.g. how to go over the elements in a sequence
- the proper **predicate**, e.g. how to determine a property of an element

use the sequence algorithms from the standard library!

But what about **heterogenous** sequences, like e.g. type-lists?

HETEROGENEOUS SEQUENCES

There is this paper by Graham Hutton

A tutorial on the universality and
expressiveness of fold

in the Journal of Functional Programming, 1999

SOME EXAMPLES

homogeneous

e.g. vector **v** of **values**

`count(v) → size_t`

`count_if(v, pred) → size_t`

`count_if(v, pred, proj) → size_t`

`for_each(v, func) → void`

`for_each(v, func, proj) → void`

`all(v, pred) → bool`

`any(v, pred) → bool`

`none(v, pred) → bool`

heterogeneous

e.g. type list <**typename... Ts**>

`size...(Ts) → size_t`

`(pred<Ts> + ... + 0) → size_t`

`(pred<proj<Ts>> + ... + 0) → size_t`

`(func<Ts>, ...) → void`

`(func<proj<Ts>>, ...) → void`

`(pred<Ts> and ...) → bool`

`(pred<Ts> or ...) → bool`

`((not pred<Ts>) and ...) → bool`

1 FIND_IF

But I need std::ranges::find_if on a type list!

```
1 static constexpr auto noIndex = std::size_t{ 0 } - 1;
2
3 template <typename T>                                     // the predicate,  T -> bool
4 struct isMarkedAsPlural {                                    // needs to be wrapped in a class for reasons
5     constexpr operator bool() const noexcept { return std::is_same_v<plural, T>; }
6 };
7
8 template <typename... Types>
9 struct format_string_translator {
10     static constexpr auto numPluralArguments = (isMarkedAsPlural<Types>{} + ... + 0);
11     static_assert(numPluralArguments <= 1, "Oops, more than one plural argument was found!");
12
13     static constexpr auto PluralIndex = findFirstIndex<isMarkedAsPlural, Types...>();
14     static_assert(numPluralArguments > 0 ? PluralIndex < sizeof...(Types) : PluralIndex == noIndex);
15 };
```

FINDFIRSTINDEX

```
1 static constexpr auto noIndex = std::size_t{ 0 } - 1;
2
3 template <typename T>
4 struct isMarkedAsPlural {
5     constexpr operator bool() const noexcept { return std::is_same_v<plural, T>; }
6 };
7
8
9 constexpr std::size_t findFirstIndex() {
10     std::size_t Result = noIndex;
11
12     return Result;
13 }
14
15 static_assert(findFirstIndex() == noIndex);
```

FINDFIRSTINDEX

```
1 static constexpr auto noIndex = std::size_t{ 0 } - 1;
2
3 template <typename T>
4 struct isMarkedAsPlural {
5     constexpr operator bool() const noexcept { return std::is_same_v<plural, T>; }
6 };
7
8
9 constexpr std::size_t findFirstIndex() {
10     std::size_t Result = noIndex + 1;
11
12     return Result - 1;
13 }
14
15 static_assert(findFirstIndex() == noIndex);
```

FINDFIRSTINDEX

```
1 static constexpr auto noIndex = std::size_t{ 0 } - 1;
2
3 template <typename T>
4 struct isMarkedAsPlural {
5     constexpr operator bool() const noexcept { return std::is_same_v<plural, T>; }
6 };
7
8 template <template <typename T> typename Predicate, typename... Types>
9 constexpr std::size_t findFirstIndex() {
10     std::size_t Result = noIndex + 1;
11
12     return (false or ... or Predicate<Types>{},           ← must be a type because of
13             Result - 1);                                ← http://eel.is/c++draft/temp.arg.template
14 }
15
16 static_assert(findFirstIndex<isMarkedAsPlural>() == noIndex);
17 static_assert(findFirstIndex<isMarkedAsPlural, void>() == noIndex);
18 static_assert(findFirstIndex<isMarkedAsPlural, plural, void>() == noIndex);
19 static_assert(findFirstIndex<isMarkedAsPlural, void, plural>() == noIndex);
```

FINDFIRSTINDEX

```
1 static constexpr auto noIndex = std::size_t{ 0 } - 1;
2
3 template <typename T>
4 struct isMarkedAsPlural {
5     constexpr operator bool() const noexcept { return std::is_same_v<plural, T>; }
6 };
7
8 template <template <typename T> typename Predicate, typename... Types>
9 constexpr std::size_t findFirstIndex() {
10     std::size_t Result = noIndex + 1;
11
12     return (false or ... or (Predicate<Types>{} ? true : false)),
13            Result - 1;
14 }
15
16 static_assert(findFirstIndex<isMarkedAsPlural>() == noIndex);
17 static_assert(findFirstIndex<isMarkedAsPlural, void>() == noIndex);
18 static_assert(findFirstIndex<isMarkedAsPlural, plural, void>() == noIndex);
19 static_assert(findFirstIndex<isMarkedAsPlural, void, plural>() == noIndex);
```

FINDFIRSTINDEX

```
1 static constexpr auto noIndex = std::size_t{ 0 } - 1;
2
3 template <typename T>
4 struct isMarkedAsPlural {
5     constexpr operator bool() const noexcept { return std::is_same_v<plural, T>; }
6 };
7
8 template <template <typename T> typename Predicate, typename... Types>
9 constexpr std::size_t findFirstIndex() {
10     std::size_t Result = noIndex + 1;
11     std::size_t Index = 0;
12
13     return (false or ... or (++Index, Predicate<Types>{} ? true : false)),
14            Result - 1;
15 }
16
17 static_assert(findFirstIndex<isMarkedAsPlural>() == noIndex);
18 static_assert(findFirstIndex<isMarkedAsPlural, void>() == noIndex);
19 static_assert(findFirstIndex<isMarkedAsPlural, plural, void>() == noIndex);
20 static_assert(findFirstIndex<isMarkedAsPlural, void, plural>() == noIndex);
```

FINDFIRSTINDEX

```
1 static constexpr auto noIndex = std::size_t{ 0 } - 1;
2
3 template <typename T>
4 struct isMarkedAsPlural {
5     constexpr operator bool() const noexcept { return std::is_same_v<plural, T>; }
6 };
7
8 template <template <typename T> typename Predicate, typename... Types>
9 constexpr std::size_t findFirstIndex() {
10     std::size_t Result = noIndex + 1;
11     std::size_t Index = 0;
12
13     return (false or ... or (++Index, Predicate<Types>{} ? Result = Index : false)),
14            Result - 1;
15 }
16
17 static_assert(findFirstIndex<isMarkedAsPlural>() == noIndex);
18 static_assert(findFirstIndex<isMarkedAsPlural, void>() == noIndex);
19 static_assert(findFirstIndex<isMarkedAsPlural, plural, void>() == 0);
20 static_assert(findFirstIndex<isMarkedAsPlural, void, plural>() == 1);
```

2

INDEX ARGUMENT

```
1 template <typename... Types>
2 std::string format(const format_string_translator<Types...> XFmt, Types &&... Args) {
3     const auto Quantity = XFmt.Quantity(
4         { reinterpret_cast<uintptr_t>(std::addressof(Args))... }
5     );
6 }
7
8 template <typename... Types>
9 struct format_string_translator {
10     static constexpr auto PluralIndex = findFirstIndex<isMarkedAsPlural, Types...>();
11
12     static plural::type Quantity(const uintptr_t (&pArgs)[ ]) noexcept {
13         if constexpr (PluralIndex != noIndex)
14             return *std::bit_cast<const plural *>(pArgs[PluralIndex]);
15         else
16             return 1;
17     }
18 };
```

This is valid code, no undefined behaviour here! 😊

3

TYPE-BASED SELECTION

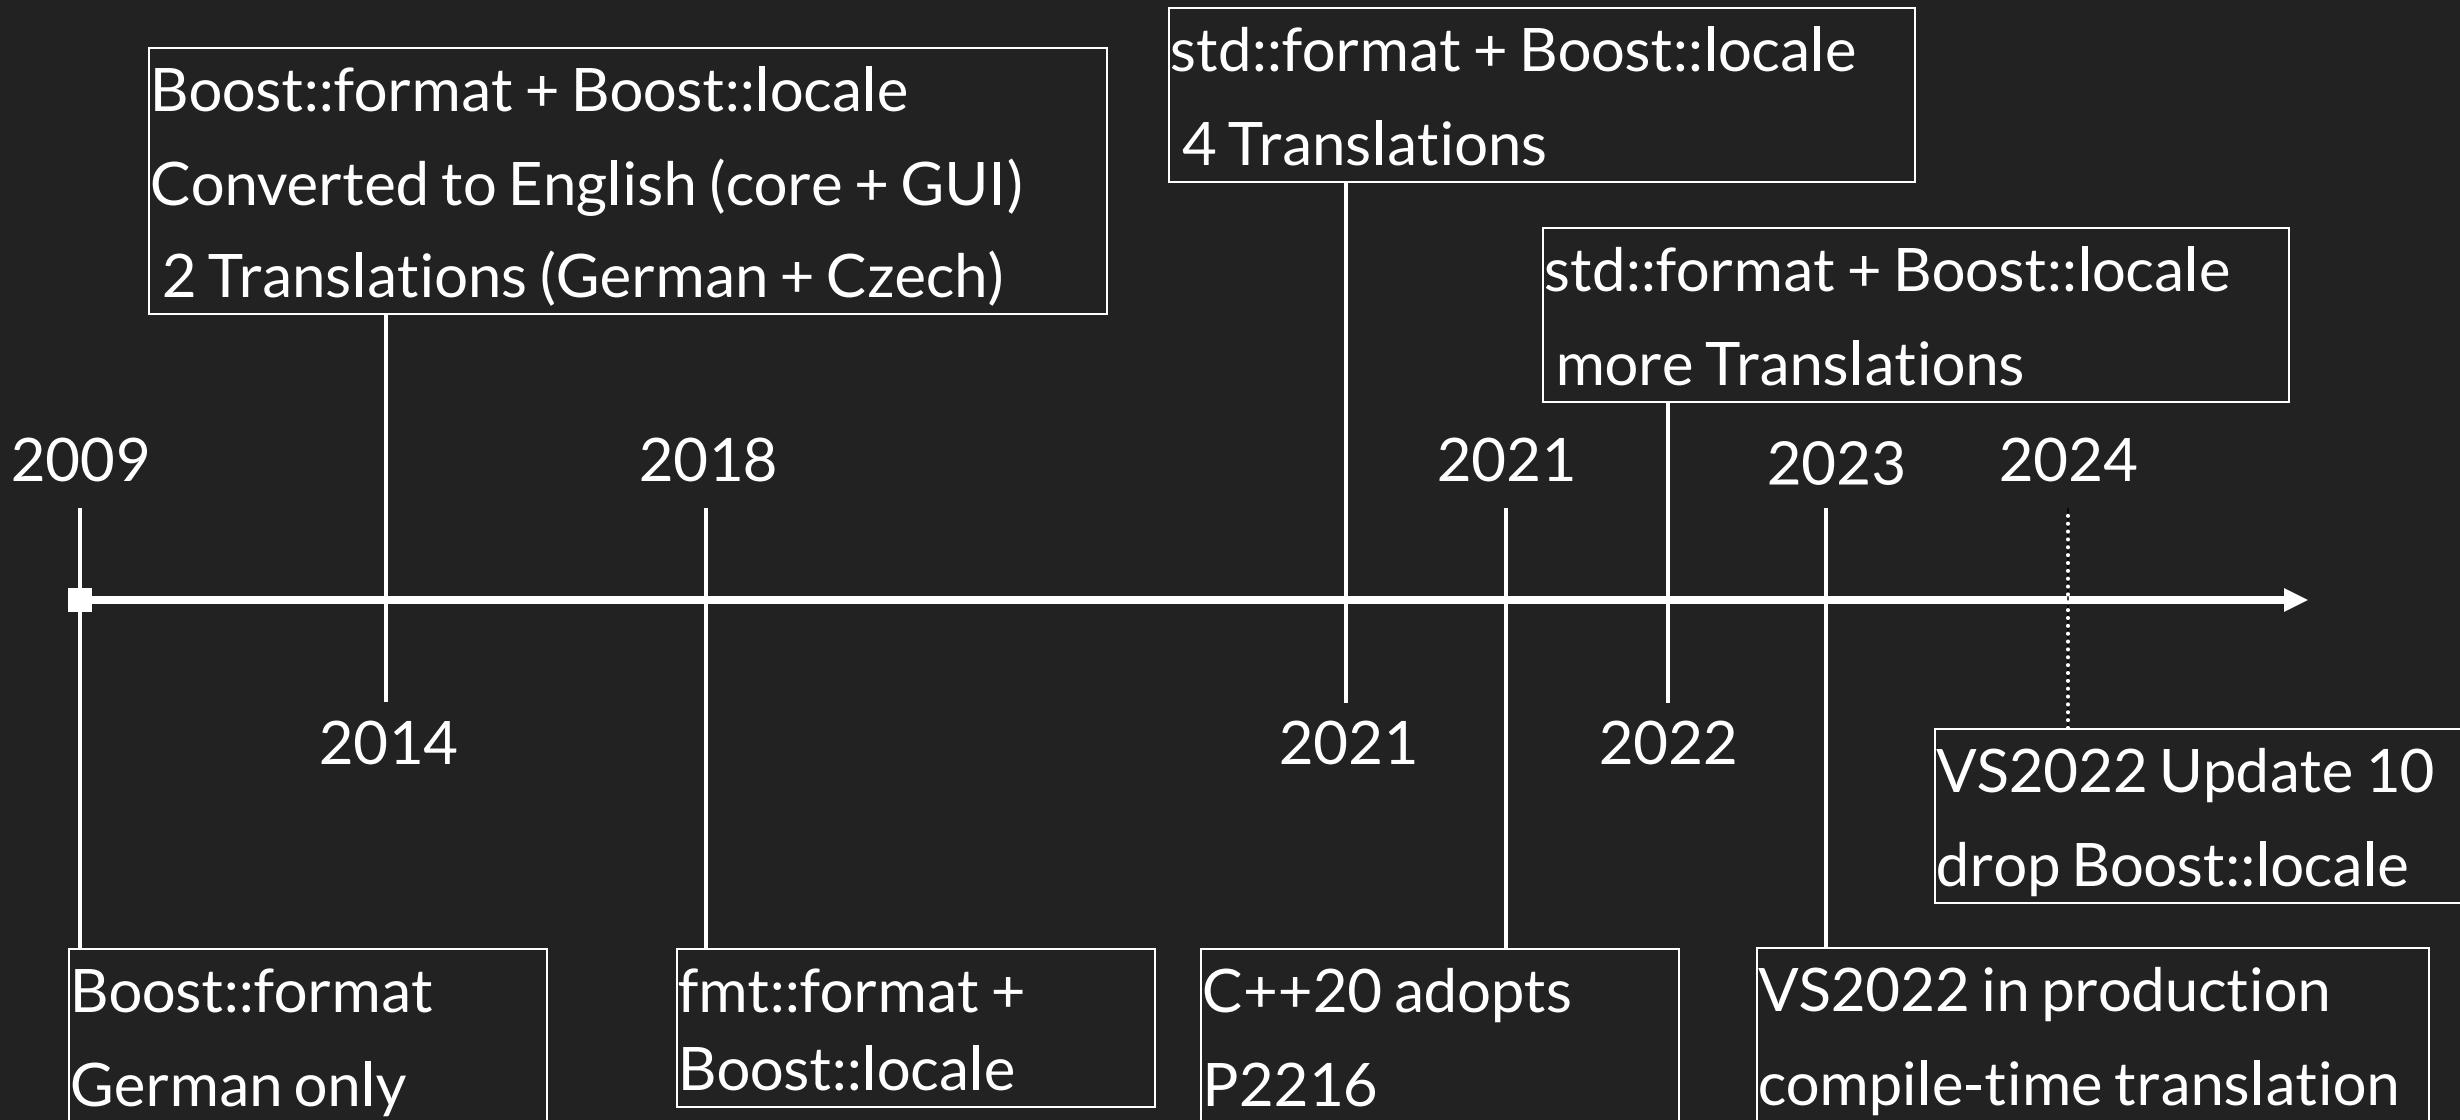

a.k.a. pattern-matching (P2688)

```
1 template <typename T>
2 struct wrapped {
3     using type = T;
4     static constexpr const type & translate(const T & t) { return t; }
5 };
6
7 template <typename Char>
8 struct wrapped<tTranslate<Char>> {
9     using type = std::basic_string_view<Char>;
10    static constexpr type translate(const tBaseTranslate<Char> & t) { return t.single(); }
11 };
12
13 template <>
14 struct wrapped<plural> {
15     using type = plural::type;
16     static constexpr type translate(const plural & t) { return t; }
17 };
```

an experiment

TIMELINE

INTEGRATION TEST

```
1 #ifndef __cpp_lib_modules
2 #define __cpp_lib_modules 202207L // use the modularized standard library 😊
3 #endif
4
5 #include "Translate.hpp"    // bring in the library: expose more than is exposed from the module
6 import utility;            // bring in a helper: a module, because why not
7
8 using namespace Translate; // slideware!
9
10 static constexpr auto Breton = utility::embed(
11 #if __has_include("br.bin")
12 # include "br.bin"         // bring in the Breton translations (~ 500) from the compiled .mo
13 #endif                      // this is a LOOONG compile-time constant (~ 40 kBytes)
14     "");                    // make it valid syntax even when it doesn't exist yet
```

INTEGRATION TEST

```
1 static constexpr auto Breton = "...";
2
3 using IntegrationDomain = tDomain<TranslationDomain("Integration")>;
4
5 static_assert(
6     [Tr = tTranslator(IntegrationDomain{}) // the frontend is in the λ capture
7      .load(LanguageId("br"), Breton)] // load and process the Breton translations
8     (uint64_t Cardinal) {           // pass in the determining cardinal value
9
10         return wlookup(Tr.DefaultLanguage(),
11                         translate(L"IntegrationContext", "Singular", "Plural", use_plural)
12                         .Digest_, // the 64-bit representation of all three strings!
13                         Cardinal);
14
15     } (0) // the cardinal 0 in the closure call
16     ==
17     L"Language Form 4" // translates to
18     // language form 4, UTF-16 because why not?
19 );
20 int main() {}
```

DEMO CODE TIME

A man with a shocked or surprised expression, with his mouth wide open and eyes wide, is pointing his right index finger upwards. He is wearing a black t-shirt with a white mustache logo. The background is a dense grid of green binary digits (0s and 1s) on a black background.

LOAD

```
1 struct tTranslator {  
2     constexpr tTranslator(const tTranslationDomain) { ... }  
3     constexpr tTranslator & load(const tLanguageId, const std::span<const char>) { ... }  
4     ...  
5 };
```

- checks the .MO header for validity
 - checks the two string tables for validity
 - locates the meta info strings
 - checks them for validity and UTF-8 conformance
 - locates the plural rules in the meta info
 - locates in **each** translation (source)
 - the singular
 - the optional context
 - the optional plural
- determines the **uniqueness** of all digests
 - locates in each translation all language forms present there (which may differ)
 - checks the validity and UTF-8 conformance of **each** language form
 - builds a string table with all forms
 - builds a lookup-table from all digests, optimized for cache-accesses
 - each translation entry points to the first correspondent language form in the string table

LOAD

```
1 struct tTranslator {  
2     ...  
3     constexpr tTranslator & load(const tLanguageId, const std::span<const char>) { ... }  
4     ...  
5 };
```

- create a second string table
 - same size
 - UTF-16 instead of UTF-8
 - different positions for each language form
- checks the plural rule for syntax and well-formedness
- parses into terminals and tokens
- checks for grammar rules
- builds an abstract syntax tree (AST)
- optimizes the AST for pattern matching

- creates a sequence of fixed-size opcodes (kind of VLIW)
- optimizes the generated program

In the end, we have (per language ID)

- one map: **digest** → 1st **string index**
- two maps: **string index** → language form **string**
- a list with the pattern matcher **program**

std::vector + std::string + std::span + views

TRANSLATE

```
1 constexpr auto translate(string-like auto Context,
2     std::string_view Singular, std::string_view Plural) -> tTranslate<char>;
3
4 constexpr auto translate(string-like auto Context,
5     std::wstring_view Singular, std::wstring_view Plural) -> tTranslate<wchar_t> {
6     return {
7         {
8             .Digest_ = hash(0, Context, ContextSeparator, Singular),
9         },
10        ...
11    };
12 }
13
14 template <typename Char>
15 struct tBaseTranslate {
16     uint64_t Digest_;           // the 64-bit representation of all strings
17 };
```

'string-like' is a concept

LOOKUP

```
1 auto lookup(const Maps &, uint64_t Digest, uint64_t Cardinal) -> std::string_view;  
2 auto wlookup(const Maps &, uint64_t Digest, uint64_t Cardinal) -> std::wstring_view;
```

- looks for the given **Digest** in the 1st map
 - gets **string index** or 'invalid'
- executes the precompiled program in a **virtual machine**, with the **Cardinal** as input
 - gets the matched language form as **plural index**
- returns the final **string_view**, taking the **string index + plural index** as final index into the 2nd map

BRETON

- 62 terminals
- 57 operations
 - arithmetic
 - comparison
 - logical
- VLIW operation (32 bits), encoding
 - up to 1 arithmetic operation + 1 exponentiation
 - up to 3 constants
 - up to 1 comparison operation (all 8 possibilities)
 - up to 1 logical operation
 - up to 2 stack pushes
 - up to 2 stack pops
 - up to 1 return
- up to 21 bytecode operations until match

TOTAL

- ≈ 500 translations (complete machine business logic)
- a couple more language forms
- lookup table size
 - 1024 entries
 - 8 bytes per entry
 - 8 entries per cacheline

More than 2 million and less than 3 million execution steps in the constant evaluator to load the compiled MO file.

move on
